#### Abstract

Intuitively, the Brownian sheet should be a Markov process if any process is'". This feeling is apparently contradicted by the fact that the sharp Markov property fails for triangles, and has led to the widely studied notion of germ-field Markov property for random fields. In this paper, it is shown for the Brownian sheet that in fact, the germ field is equal to the sharp field for almost every curve $y=f(x)$ (when $f$ is drawn at random according to Wiener measure on the set of continuous functions), and thus the two Markov properties coincide in this case. This result follows from sufficient conditions on $f$ for equality of the two fields. In the case that $f$ satisfies a weak regularity assumption (implied by Banach's classical condition (T1)), we give necessary and sufficient conditions on $f$ for equality of the two fields. When $f$ has bounded variation, the condition is that $f$ be singular with respect to Lebesguemeasure.

## 1. Introduction.

The Brownian sheet has long been known to satisfy the sharp Markov property with respect to finite unions of rectangles (see [W1]; a detailed proof for planar processes with independent increments is given in [Ru]). However, this property fails for the triangle $\left\{\left(t_{1}, t_{2}\right) \in \mathbf{R}_{+}^{2}: t_{1}+t_{2} \leq 1\right\}[W 1]$, leaving the impression that the sharp Markov property is valid only for a very restricted class of sets. In contrast, the weaker germ-field Markov property is valid for all open sets in the plane ([Ro], [ Nu ]).

Thus, for many sets $A$ (e.g. the triangle), the germ-field $\underline{=}(\partial A)$ of the boundary is strictly larger than the sharp field $\underset{=}{\mathrm{F}}(\partial \mathrm{A})$, whereas for curves $\Gamma$ which are a finite union of horizontal or vertical segments, $\underset{\underline{F}}{(\Gamma)}=\underline{\underline{G}}(\Gamma)$. One might think that these were the only curves for which this equality is valid. However, Dalang and Russo [DR] exhibited separation lines containing no vertical or horizontal segment for which the two fields are equal; [DR] also contains a detailed study of the structure of $\underset{\underline{F}}{\mathbf{F}}(\Gamma)$ and $\underset{=}{G}(\Gamma)$ when $\Gamma$ is a separation line.

The motivation for the research reported here is to show that, in a sense, the "generic" case is equality of the germ and sharp fields. More precisely, we consider curves $\Gamma$ which are the graphs of continuous functions $y=\phi(x)$, where $\phi \in \mathbf{C}\left(\mathbf{R}_{+}, \mathbb{R}\right)$. We show that if $\phi$ is drawn at random according to Wiener measure on $C\left(\mathbf{R}_{+}, \mathbb{R}\right)$, then with probability one, $\underline{=}(\Gamma)=\underset{=}{F}(\Gamma)$ (see Corollary 4.13).

This result is obtained in several steps. First of all, we show that $\underset{=}{\mathbf{G}}(\Gamma)$ is also the minimal splitting field $\underset{=}{M}(\Gamma)$ (Theorem 2.1), by using a result of Nualart [Nu]. We then give a description of the generators of the minimal splitting field (Theorem 3.8), which corresponds to the "vertical and horizontal shadow" description for domains with smooth boundaries ([W1], [W3], [WZ]). It is then possible to give conditions on $\phi$ (Assumption 4.5, Remark 4.11) which ensure that $\underset{\underline{F}}{\boldsymbol{F}}(\Gamma)=\underline{\underline{G}}(\Gamma)$ (Theorem 4.9). In particular, if $\phi$ has almost everywhere an infinite upper-right Dini derivative, then the two fields are equal; this is also the case when $\phi$ has bounded variation and is singular.

It is more difficult to obtain necessary conditions on $\phi$ for equality of $\underset{\underline{F}}{\boldsymbol{F}}(\Gamma)$ and $\underline{\underline{G}}(\Gamma)$. We address this question by giving an explicit representation of the closed Gaussian subspace $G(\Gamma)$ spanned by the generators of the germ field (Theorem 5.5), generalizing a result of Dalang and Russo [DR]. Under a regularity assumption on $\Gamma$ (Assumption 5.7), we give conditions that elements of $G(\Gamma)$ must satisfy in order to be
$\underset{=}{F}(\Gamma)$-measurable (Proposition 5.12). This regularity assumption is implied by Banach's condition (T1) that almost every level set of $\phi$ be finite. Under this assumption, we can then provide necessary and sufficient conditions for equality of $\underset{=}{F}(\Gamma)$ and
 and only if $\phi$ is singular with respect to Lebesgue-measure.

In Section 2 below, we summarize the principal notations and definitions we will be using, and prove equality of the germ and minimal splitting fields.

## 2. The germ field of a continuous curve is the minimal splitting field.

Throughout this paper, $\mathbf{T}=\mathbf{R}_{+}^{2}$ will denote the non-negative quadrant in the plane. If $t=\left(t_{1}, t_{2}\right) \in T, R_{1}$ will denote the set $\left\{\left(s_{1}, s_{2}\right) \in T: s_{1} \leq t_{1}\right.$ and $\left.s_{2} \leq t_{2}\right\}$. Lebesgue measure on $\mathbf{R}_{+}^{2}$ will be denoted dt whereas Lebesgue-measure on $\mathbf{R}$ will be denoted $\mu_{1}$ (a measure $\mu_{2}$ will be defined in Section 4).

Let $(\Omega, \underline{F}, \mathrm{P})$ be a complete probability space on which a Brownian sheet $\left(W_{t}, t \in T\right)$ is defined. The Brownian sheet can be regarded as he distribution function of a white noise $W$ on $T$, that is $W_{t}=W\left(R_{\nu}\right)$ a.s. (see [W3; chap.3] for a complete definition).

Given $A \subset T$, the sharp field $\underset{\underline{H}}{\underline{H}}(A)$ of $A$ is defined by $\underset{\underline{H}}{(A)}=\sigma\left(W_{t}, t \in A\right)$, whereas $H(A)$ denotes the closed linear span of $\left\{W_{t}, t \in A\right\}$ (in $L^{2}(\Omega, F, P)$ ). The germ field $\underline{\underline{G}(A)}$ is defined by

$$
\underline{\underline{G}}(\mathrm{~A})=\bigcap_{\infty} \underset{=}{\mathrm{F}_{1}\left(\mathrm{~A}_{\varepsilon}\right),}
$$

where $A_{\varepsilon}$ is an $\varepsilon$-neighborhood of $A$. If we set

$$
G(A)=\bigcap_{\infty} \mathrm{H}\left(\mathrm{~A}_{\varepsilon}\right),
$$

A $\sigma$-field $\underset{\underline{A}}{\text { A }}$ such that $\underset{\underline{H}}{\mathrm{H}}(\mathrm{A})$ and $\underset{\underline{H}}{\mathrm{H}}\left(\mathrm{A}^{\mathrm{C}}\right)$ are conditionally independent given $\underset{\underline{A}}{\text { A }}$ is called a splitting field for A . The following properties are well-known.
(2.1) $\underset{\underline{H}}{\underline{H}}(\mathbf{A}) \cap \underset{\underline{\underline{H}}}{\left(A^{c}\right) \subset} \subset \underline{\underline{A}}$, for any splitting field $\underset{\underline{A}}{\text { A }}$ of ([Mc; Sect.6], [W1]);
(2.2) $\underline{\underline{G}(\partial A)}$ is a splitting field for all open sets (see [Ro; Chap. 3 §5] for bounded open sets, [Nu; Th. 3.1] in the general case);
(2.3) $\underset{=}{\mathrm{H}}(\partial \mathrm{A})$ is a splitting field for A when A is a finite union of rectangles with sides parallel to the coordinate axes [Ru; Th.7.5];
(2.4) $\underset{=}{\mathrm{H}}(\partial \mathrm{A})$ is not a splitting field when A is the triangular region $\left\{\left(s_{1}, s_{2}\right) \in \mathrm{T}\right.$ : $\left.s_{1}+s_{2}<1\right\}$ ([W1], [W3; p.399]).
Property (2.2) is known as the germ-field Markov property of the Brownian sheet. We say that the Brownian sheet has the sharp Markov property with respect to $\mathrm{A} \subset \mathrm{T}$ provided $\underset{\underline{H}}{\mathrm{H}}(\partial \mathrm{A})$ is a splitting field for A (see [W2]). Because of (2.4), it has widely been assumed in the literature that the Brownian sheet has the sharp Markov property only with respect to a very restricted class of sets (e.g. those in (2.3)). In fact, as mentioned in the introduction, we will show that the case $\underline{\underline{G}}(\partial A)=\underline{\underline{F}}(\partial A)$ is the "generic" case, at least when $\partial \mathrm{A}$ is the graph of a continuous function from $\mathbf{R}_{+}$to $\mathbf{R}_{+}$.

Throughout this paper, we work with a continuous function $\phi:[0, \bar{u}] \rightarrow \mathbf{R}$, such that $\overline{\mathrm{u}}>0, \phi(\overline{\mathrm{u}})=0$, and

$$
0 \leq u<\bar{u} \Rightarrow \phi(u)>0 .
$$

The graph $\Gamma$ of $\phi$, defined by $\Gamma=\{(u, \phi(u)): 0 \leq u \leq \bar{u}\}$ is a continuous curve, with two-dimensional Lebesgue measure 0 , that splits $\mathbf{R}_{+}^{2}$ into two disjoint open connected components. The bounded component is

$$
D_{1}=\left\{t=\left(t_{1}, t_{2}\right) \in R_{+}^{2}: t_{1}<\bar{u}, t_{2}<\phi\left(t_{1}\right)\right\},
$$

and the unbounded component is

$$
\overline{\mathrm{D}}_{1}^{c}=\left\{\mathrm{t}=\left(\mathrm{t}_{1}, \mathrm{t}_{2}\right) \in \mathbf{R}_{+}^{2}: \mathrm{t}_{1}>\overline{\mathrm{u}} \text { or }\left(\mathrm{t}_{1} \leq \overline{\mathrm{u}} \text { and } \mathrm{t}_{2}>\phi\left(\mathrm{t}_{1}\right)\right)\right\} .
$$

2.1. Theorem. The germ field $\underset{\underline{G}}{(\Gamma)}$ ) of $\Gamma$ is the minimal splitting field for $\underset{=}{F}\left(D_{1}\right)$ and $\underset{\underline{F}}{\left(\bar{D}_{1}^{c}\right)}$. In particular, $\underline{\underline{G}}(\Gamma)=\underline{\underline{H}}\left(\mathrm{D}_{1}\right) \cap \underline{\underline{H}}\left(\overline{\mathrm{D}}_{1}^{\mathrm{c}}\right)$.

Proof. This proof is similar to that of [DR; Theorem 3.1], which covers the case where $f$ is non-increasing. It is sufficient to prove that

$$
\begin{equation*}
G(\Gamma)=H\left(D_{1}\right) \cap H\left(\bar{D}_{1}^{c}\right), \tag{2.5}
\end{equation*}
$$

since then, by [M; Lemma 3.3],

$$
\underline{\underline{G}}(\Gamma)=\sigma(G(\Gamma))=\sigma\left(H\left(D_{1}\right)\right) \cap \sigma\left(H\left(\bar{D}_{1}^{c}\right)\right)=\underline{\underline{H}}\left(\mathrm{D}_{1}\right) \cap \underset{\underline{H}}{H}\left(\overline{\mathrm{D}}_{1}^{c}\right),
$$

and the conclusion will follow from (2.1) and (2.2).

Let

$$
K=\left\{h: T \rightarrow R: h(\cdot)=\int_{R_{0}} g(s) d s, g \in L^{2}(T, d t)\right\}
$$

be the reproducing kernel Hilbert space of the Brownian sheet, with the norm

$$
\left\|\int_{R_{0}} g(s) d s\right\|_{K}=\|g\|_{L^{2}(T, d t)}
$$

According to [ Nu ; Proposition 2.2], the condition below is equivalent to (2.5).
(2.6) For $\Delta \in\left\{D_{1}, \bar{D}_{1}^{c}\right\}$, for each $\eta_{1} \in K$ with support included in $\bar{\Delta}$, and for $\varepsilon>0$, there is $\eta_{2} \in K$ with support included in $\Delta$ such that $\left\|\eta_{1}-\eta_{2}\right\|_{\mathrm{K}}<\varepsilon$.

To check (2.6), fix $\eta \in K$ with support in $\bar{D}_{1}$ (respectively $D_{1}$ ), and $g \in L^{2}(T, d t)$ such that

$$
\eta(t)=\int_{R_{t}} g(s) d s, t \in T
$$

For $\alpha>0, \operatorname{set} g^{\alpha}\left(s_{1}, s_{2}\right)=g\left(s_{1}, \alpha s_{2}\right)$ and

$$
\eta^{\alpha}(t)=\int_{R_{t}} g^{\alpha}\left(s_{1}, s_{2}\right) d s_{1} d s_{2}, \quad\left(s_{1}, s_{2}\right) \in T
$$

Note that $\eta^{\alpha}\left(t_{1}, t_{2}\right)=\eta\left(t_{1}, \alpha t_{2}\right) / \alpha$, and for $\alpha>1$ (resp. $\alpha<1$ ) the support of $\eta^{\alpha}$ is contained in $D_{1}$ (resp. $\bar{D}_{1}^{c}$; note that this is due to the fact that $\Gamma$ contains no vertical segments, and so this proof does not cover the case of [DR; Theorem 3.1], nor viceversa). So (2.6) holds since $\left\|g-g^{\alpha}\right\|_{L^{2}}$ converges to 0 as $\alpha$ approaches 1.

## 3. The generators of the minimal splitting field.

The generators of the minimal spliting field of a domain with a smooth boundary were determined in [W1], [W3; Th. 3.11] and with a piecewise monotone boundary in [WZ; Prop. 1]. In these cases, the minimal splitting field is generated by the white noise measures of the vertical and horizontal shadows of portions of the boundary, and the proof can be carried out by drawing pictures [W3; Th. 3.11]. The ideas in the smooth case are essentially valid in our setting. However, since we make no regularity assumptions on $\phi$ or $\Gamma$, precise topological definitions and formal proofs are necessary. Let

$$
s_{2}=\left\{\left(t_{1}, t_{2}\right) \in T: \text { there is }\left(s_{1}, s_{2}\right) \in \Gamma \text { with } s_{1} \geq t_{1} \text { and } s_{2}=t_{2}\right\}
$$

be the 'horizontal shadow'" of $\Gamma$. Note that $S_{2}=D_{1} \cup \bar{D}_{2}$, where $D_{2}=\operatorname{int}\left(S_{2} \cap \bar{D}_{1}^{c}\right)$.

An analogous definition of the vertical shadow $S_{1}$ of $\Gamma$ leads to the set $\bar{D}_{1}$.
3.1. Proposition. For $0 \leq u \leq \bar{u}$, set $S_{1}^{u}=\left\{s \in D_{1}: s_{1} \leq u\right\}$ and $W_{u}^{1}=W\left(S_{1}^{u}\right)$. Then

$$
W_{u}^{1} \in \underset{=}{\mathrm{H}}\left(\mathrm{D}_{1}\right) \cap \underset{\underline{H}}{\underline{\mathrm{H}}}\left(\overline{\mathrm{D}}_{1}^{c}\right) .
$$

Proof. Observe that

$$
S_{1}^{u}=\left\{s \in T: 0 \leq s_{1} \leq u, 0 \leq s_{2}<\phi\left(s_{1}\right)\right\}
$$

For $n \in \mathbb{N}$ and $i=0, \ldots, n$, set $a_{i}=i u / n$, and

$$
\begin{align*}
m_{i}=\min _{a_{i} \leq v \leq a_{i+1}} \phi(v), \quad M_{i} & =\max _{a_{i} \leq v \leq a_{i+1}} \phi(v), \\
s_{n}^{1}=\frac{1}{n} \sum_{i=0}^{n-1} m_{i}, \quad s_{n}^{2} & =\frac{1}{n} \sum_{i=0}^{n-1} M_{i}, \\
Y_{n}^{1}=\sum_{i=0}^{n-1}\left(W_{a_{i+1}, m_{i}}-W_{a_{i}, m_{i}}\right), \quad Y_{n}^{2} & =\sum_{i=0}^{n-1}\left(W_{a_{i+1}, M_{i}}-W_{a_{i}, M_{i}}\right) . \tag{3.1}
\end{align*}
$$

Then clearly $Y_{n}^{1} \in \underset{=}{H}\left(D_{1}\right), Y_{n}^{2} \in \underset{\underline{H}}{H}\left(\bar{D}_{1}^{c}\right)$, and for $i=1,2$,

$$
E\left(\left(Y_{n}^{i}-W_{u}^{1}\right)^{2}\right)=\left|s_{n}^{i}-\int_{0}^{u} \phi(v) d v\right| \rightarrow 0
$$

as $n \rightarrow \infty$, since $s_{n}^{1}$ (respectively $s_{n}^{2}$ ) is the lower (resp. upper) Riemann sum of $\phi$ and $\phi$ is continuous. This completes the proof.

Proposition 3.1 essentially takes care of vertical shadows. To get horizontal shadows, define $p: S_{1} \cup S_{2} \rightarrow[0, \bar{u}]$ by

$$
p\left(t_{1}, t_{2}\right)=\inf \left\{u \geq t_{1}: \phi(u)=t_{2}\right\}
$$

This mapping has interesting measurability properties.

### 3.2. Lemma. (a) The function $p$ is Borel.

(b) For any rectangle $\theta=[a, b] \times[c, d]$, contained in $D_{1}$ or in $D_{2}$, or more generally, for any open subset $\theta$ of $D_{1} \cup D_{2}, p(\theta)$ is a Borel subset of $D_{1} \cup D_{2}$.
(c) $\mathrm{p}\left(\mathrm{D}_{1}\right) \cap \mathrm{p}\left(\mathrm{D}_{2}\right)=\varnothing$.

Proof. (a) For $u, v \in[0, \bar{u}]$, with $u \leq v$, set

$$
L(u, v)=\max _{u \leq x \leq v} \phi(x), \quad l(u, v)=\min _{u \leq x \leq v} \phi(x)
$$

(these notations will be used throughout the paper). Observe that for $0 \leq v \leq \bar{u}$,

$$
\begin{equation*}
\left\{s \in S_{1} \cup S_{2}: p(s) \leq v\right\}=\left\{s \in T: s_{1} \leq v, l\left(s_{1}, v\right) \leq s_{2} \leq L\left(s_{1}, v\right)\right\} \tag{3.2}
\end{equation*}
$$

This is clearly a Borel set, since $l(\cdot, v)$ and $L(\cdot, v)$ are continuous functions.
(b) It is sufficient to prove (b) when $\theta$ is a closed rectangle in $D_{1}$ or $D_{2}$. Indeed, any open subset of $D_{1} \cup D_{2}$ is a countable union of such rectangles, and the image of a union is the union of the images. So set

$$
\theta=[a, b] \times[c, d], \quad a<b, \quad c<d,
$$

and suppose for example that $\theta \subset D_{1}$ (the case $\theta \subset D_{2}$ is similar). Set $u_{0}=p((b, d))$, $\left.\mathrm{u}_{1}=\mathrm{p}(\mathrm{b}, \mathrm{c})\right)$, and

$$
\tau(u)=\inf \left\{v \geq u_{0}: l\left(u_{0}, v\right)=l\left(u_{0}, u\right)\right\}, \quad u_{0} \leq u \leq u_{1} .
$$

Then $l\left(u_{0}, \tau(u)\right)=l\left(u_{0}, u\right), u_{0} \leq u \leq u_{1}$, and

$$
p(\theta)=\left\{u \in\left[u_{0}, u_{1}\right]: \tau(u)=u\right\} .
$$

Since $u \mapsto \tau(u)$ is easily seen to be left-continuous, $p(\theta)$ is Borel.
(c) Suppose $s \in D_{1}, t \in D_{2}$ and $p(s)=p(t)$. Then $s_{2}=t_{2}$ by definition of $p$, so we suppose for instance that $s_{1}<t_{1}$. Then $\phi\left(s_{1}\right)>s_{2}$ since $s \in D_{1}$ and $\phi\left(t_{1}\right)<t_{1}$ since $t \in D_{2}$. By the Intermediate Value Theorem, there is $\left.u \in t\right] s_{1}, t_{1}\left[\right.$ with $\phi(u)=s_{2}=t_{2}$. But then $\mathrm{p}(\mathrm{s}) \leq \mathrm{u}<\mathrm{t}_{1} \leq \mathrm{p}(\mathrm{t})$, a contradiction.
3.3. Proposition. For $0 \leq u \leq \bar{u}$, let

$$
S_{2}^{u}=\left\{s \in S_{1} \cup S_{2}: p(s) \leq u\right\}
$$

denote the horizontal shadow of $\left\{(v, \phi(v): v \leq u\}\right.$, and set $W_{u}^{2}=W\left(S_{2}^{u}\right)$. Then

$$
W_{u}^{2} \in \underset{\underline{H}}{H}\left(D_{1}\right) \cap \underset{\underline{H}}{H}\left(\bar{D}_{1}^{c}\right) .
$$

Proof. The region $S_{2}^{u}$ is characterized in (3.2). In particular, $S_{2}^{u}=E_{1} \backslash E_{2}$, where

$$
\begin{aligned}
& \mathrm{E}_{1}=\left\{\left(\mathrm{s}_{1}, \mathrm{~s}_{2}\right): 0 \leq \mathrm{s}_{1} \leq \mathrm{u}, \mathrm{~s}_{2} \leq \mathrm{L}\left(\mathrm{~s}_{1}, \mathrm{u}\right)\right\} \\
& \mathrm{E}_{2}=\left\{\left(\mathrm{s}_{1}, \mathrm{~s}_{2}\right): 0 \leq \mathrm{s}_{1} \leq \mathrm{u}, \mathrm{~s}_{2}<l\left(\mathrm{~s}_{1}, \mathrm{u}\right)\right\}
\end{aligned}
$$

So we only need to show that $W\left(E_{i}\right) \in \underset{\underline{H}}{H}\left(D_{1}\right) \cap \underset{=}{\mathbf{H}}\left(\bar{D}_{1}^{c}\right), i=1,2$. We only carry out the proof for $\mathrm{i}=1$, since the case $\mathrm{i}=2$ is similar.

To show that $W\left(E_{1}\right)$ is $\underset{=}{\mathrm{H}}\left(\overline{\mathrm{D}}_{1}^{c}\right)$-measurable, we proceed as in the proof of Proposition 3.1, by approximating the area of the region $E_{1}$ by upper Riemann sums. The variables which correspond to the $Y_{n}^{2}$ in (3.1) are clearly $\left.\underset{\underline{=}}{\mathrm{H}} \overline{\mathrm{D}}_{1}^{\mathrm{c}}\right)$-measurable, so $\mathrm{W}\left(\mathrm{E}_{1}\right)$
is too.
To check that $W\left(E_{1}\right)$ is $\underset{=}{\mathrm{H}}\left(\mathrm{D}_{1}\right)$-measurable, we must take care to use only points in $\bar{D}_{1}$ in the approximation. This will be achieved using a "horizontal" discretisation instead of a "vertical" one. Set $a=L(u, u)=\phi(u), b=L(0, u), s_{1}^{0}=u$, and for $n \in \mathbb{N}$ and $\mathrm{i}=1, . ., \mathrm{n}-1$,

$$
\begin{gathered}
s_{2}^{i}=a+i(b-a) / n, \\
s_{1}^{i}=\inf \left\{v \leq u: L(v, u)=s_{2}^{i}\right\}
\end{gathered}
$$

( $s_{1}^{i}$ exists because $L(\cdot, u)$ is continuous). Now set

$$
Y_{n}^{2}=\sum_{i=0}^{n-1}\left(W_{s_{1}^{i}, L\left(s_{1}^{i}, u\right)}-W_{s_{1}^{i+1}, L\left(s_{1}^{i}, u\right)}\right)
$$

Clearly, $\mathrm{E}\left(\left(\mathrm{W}\left(\mathrm{E}_{1}\right)-\mathrm{Y}_{\mathrm{n}}^{2}\right)^{2}\right) \leq \mathrm{u} / \mathrm{n}$, so the proof will be complete if we show that $\mathrm{Y}_{n}^{2}$ is $\underset{=}{H}\left(D_{1}\right)$-measurable. This will be the case if we prove that $\phi\left(s_{1}^{i}\right)=L\left(s_{1}^{i}, u\right)$, $\mathrm{i}=0, \ldots, \mathrm{n}-1$, because in this case we will have

$$
\left(s_{1}^{i}, L\left(s_{1}^{i}, u\right)\right) \in \bar{D}_{1} \text { and }\left(s_{1}^{i+1}, L\left(s_{1}^{i}, u\right)\right) \in D_{1}(i \neq n)
$$

By definition of $s_{1}^{i}$,

$$
\begin{equation*}
v \geq s_{1}^{i} \Rightarrow L(v, u) \leq s_{2}^{i} \Rightarrow \phi(v) \leq s_{2}^{i} \tag{3.3}
\end{equation*}
$$

and $v<s_{1}^{i} \Rightarrow L(v, u)>s_{2}^{i}$. Thus, by definition of $L(\cdot, \cdot)$, for any $\varepsilon>0$, there is $\left.v^{i} \in\right] s_{1}^{i}-\varepsilon, s_{1}^{i}\left[\right.$ such that $\phi\left(v^{i}\right)>s_{2}^{i}$. But then continuity of $\phi$ and (3.3) imply $\phi\left(s_{1}^{i}\right)=s_{2}^{i}=L\left(s_{1}^{i}, u\right)$. This completes the proof.

The image under the mapping $p$ of Lebesgue-measure on $S_{1} \cup S_{2}$ is a measure $\mu_{2}$ on the $\sigma$-algebra $\underset{=}{B}([0, \bar{u}])$ of Borel sets of $[0, \bar{u}]$, defined by

$$
\mu_{2}(\mathrm{I})=\text { Lebesgue-measure of } \mathrm{p}^{-1}(\mathrm{I}), \mathrm{I} \in \underset{=}{\mathrm{B}}([0, \overline{\mathrm{u}}]) .
$$

If we consider that white noise $W$ is an $L^{2}(\Omega, \underset{=}{F}, P)$-valued measure (i.e. a vector measure), its image $\hat{W}$ under $p$ is an orthogonal measure on [ $0, \bar{u}$ ] with variance $\mu_{2}$, i.e.

$$
\mathrm{I} \cap \mathrm{~J}=\phi, \mathrm{I}, \mathrm{~J} \in \underset{\underline{B}}{\mathrm{~B}}([0, \overline{\mathrm{u}}]) \Rightarrow \mathrm{E}(\hat{\mathrm{~W}}(\mathrm{I}) \hat{\mathrm{W}}(\mathrm{~J}))=0,
$$

and for Borel $\left.f \in L^{2}([0, \bar{u}]), d \mu_{2}\right)$,

$$
E\left(\left(\int_{[0, \bar{u}]} f(u) d \hat{W}_{u}\right)^{2}\right)=\int_{[0, \bar{u}]} f^{2}(u) d \mu_{2}(u) .
$$

If one wants to avoid images of vector measures, one can simply consider that

$$
\int_{[0, \pi]} f(u) d \hat{W}_{u}
$$

is a shorthand notation for

$$
\int_{s_{1} \cup S_{2}} f(p(t)) d W_{t} .
$$

3.4. Proposition. Suppose $f \in L^{2}\left([0, \bar{u}], d \mu_{2}\right)$ is Borel. Then

$$
\begin{equation*}
\int_{[0, \widetilde{u}]} f(v) d \hat{W}_{v} \in \underset{=}{H}\left(D_{1}\right) \cap \underset{=}{H}\left(\bar{D}_{1}^{c}\right) . \tag{3.4}
\end{equation*}
$$

Proof. Observe that if $f=I_{[0, u]}\left(I_{[0, u]}\right.$ is the indicator function of $\left.[0, u]\right)$, then

$$
\int_{[0, \pi]} f(v) d \hat{W}_{v}=W_{u}^{2}
$$

so the conclusion in this case follows from Proposition 3.3. This implies (3.4) for all $f$ which are a finite linear combination of indicator functions of intervals. Now suppose ( $f_{n}, n \in N$ ) is an increasing sequence of uniformly bounded Borel functions that satisfy (3.4), and set $f=\lim _{n \rightarrow \infty} f_{n}$. Then $f_{n} \rightarrow f$ in $L^{2}([0, \bar{u}])$, d $\mu_{2}$ ) so

$$
\int_{[0, \pi]} f_{n} d \hat{W} \rightarrow \int_{[0, \pi]} f d \hat{W} \text { in } L^{2}(\Omega, \underset{=}{F}, P),
$$

so $f$ satisfies (3.4). We now apply the Monotone Class Theorem (see [DM; I.21]) to see that (3.4) holds for all bounded Borel functions. If $f \geq 0$ is Borel and $\left.f \in L^{2}([0, \bar{u}]), d \mu_{2}\right)$, then

$$
f=\lim _{n \rightarrow \infty} \min (f, n) \text { in } L^{2}\left([0, \bar{u}], d \mu_{2}\right)
$$

so (3.4) again holds in this case. Finally, to conclude for general Borel $f \in L^{2}\left([0, \bar{u}], d \mu_{2}\right)$, simply decompose $f$ into its positive and negative parts.

### 3.5. Lemma. Set

$$
\begin{gathered}
\underline{\mathrm{G}}_{\text {in }}^{1}=\sigma\left(\mathrm{W}(\theta), \theta \subset S_{1}, \theta \text { open }\right) \\
\underline{\underline{G}}_{\text {out }}^{1}=\sigma\left(\int_{[0, \widetilde{u}]} f \mathrm{~L}_{\mathrm{p}\left(\mathrm{D}_{2}\right)} \mathrm{d} \hat{W}, \mathrm{f} \text { bounded Borel }\right)
\end{gathered}
$$

(recall that $p\left(D_{2}\right)$ is a Borel set by Lemma 3.2 (b)). Then $\underline{\underline{G}}^{1}$ and $\underline{\underline{G}}^{1}{ }_{o u t}$ are independent and $\underset{\underline{I}}{H}\left(D_{1}\right)=\underline{\underline{G}}_{i n}^{1} \vee \underline{\underline{G}}$ out.

Proof. Observe that for each open set $\theta \subset D^{1}$ and for each bounded Borel function $f$,

$$
\begin{aligned}
E\left(W(\theta) \int_{[0, \pi]} f L_{p\left(D_{2}\right)} d \hat{W}\right) & =E\left(W(\theta) \int_{S^{1} \cup S^{2}} f(p(s)) I_{D^{2}}(s) d W_{s}\right) \\
& =0
\end{aligned}
$$

since $\theta \cap \mathrm{D}^{2}=\phi$. Since we are working with Gaussian random variables, $\mathrm{G}_{\mathrm{in}}{ }^{1}$ and $\mathrm{G}_{\mathrm{out}}^{1}$ are independent. To check the second statement of the lemma, it is sufficient to show that if $t \in D_{1}$, then

$$
W_{t}=W\left(D_{1} \cap \operatorname{int} R_{\nu}\right)+\int_{[0, \pi]} I_{p\left(i n t R_{J}\right)} I_{p\left(D_{2}\right)} d \hat{W},
$$

where int $R_{t}$ is the interior of the rectangle $R_{t}$. Now for $t \in D_{1}$,

$$
\begin{aligned}
W_{t}-W\left(D_{1} \cap \operatorname{int} R_{v}\right) & =W\left(\left(\operatorname{int} R_{v}\right) \backslash\left(D_{1} \cap \operatorname{int} R_{t}\right)\right) \\
& =W\left(D_{2} \cap \operatorname{int} R_{t}\right) \\
& =\int_{[0, \bar{u}]} I_{p\left(\operatorname{int} R_{v}\right)} I_{p\left(D_{2}\right)} d \hat{W}
\end{aligned}
$$

(in the second equality above, we have used the fact that the Lebesgue measure of $\Gamma$ is zero).

We now recall the following lemma concerning conditional expectations of Gaussian random variables.
3.6. Lemma. Let $\mathrm{H}^{1}$ and $\mathrm{H}^{2}$ be two closed subspaces of a Gaussian space H .
(a) Suppose $\mathrm{H}^{1}$ and $\mathrm{H}^{2}$ are orthogonal and $Y \in \mathrm{H}$ is orthogonal to $\mathrm{H}^{1}$. Then

$$
\mathrm{E}\left(\mathrm{Y} \mid \sigma\left(\mathrm{H}^{1}\right) \vee \sigma\left(\mathrm{H}^{2}\right)\right)=\mathrm{E}\left(\mathrm{Y} \mid \sigma\left(\mathrm{H}^{2}\right)\right)
$$

(b) Suppose $G \subset \mathrm{H}^{1} \cap \mathrm{H}^{2}$ is also a closed subspace, such that $\mathrm{pr}_{\mathrm{G}}(\mathrm{Y})=\mathrm{pr}_{\mathrm{H}^{2}}(\mathrm{Y})$, for all $Y \in H^{1}$ (pr denotes orthogonal projection). Then $\sigma(G)$ is a splitting field for $\sigma\left(\mathrm{H}^{\mathrm{l}}\right)$ and $\sigma\left(\mathrm{H}^{2}\right)$.

Proof. (a) is a consequence of the fact that conditional expectations of Gaussian random variables are orthogonal projections, and (b) is a standard result (see [C; Lemma 5]).
3.7. Lemma. Suppose $t \in \bar{D}_{1}^{c}$. Then
(a) there is a $G^{1}{ }^{1}$-measurable variable $Z_{\ell}$ such that

$$
E\left(W_{t} \mid \underline{=}\left(D_{1}\right)\right)=W\left(D_{1} \cap R_{v}\right)+Z_{t} .
$$

(b) $W\left(D_{1} \cap R_{v}\right)=W_{t_{1}}^{1}-\int I_{p\left(\left\{s \in D_{1}: s_{1} s t_{1}, \varepsilon_{2}>t_{2}\right)\right)} d \hat{W}$

Proof. (a) Note that $W_{t}=Y_{1}+Y_{2}+Y_{3}$, where

$$
Y_{1}=W\left(R_{t} \cap D_{1}\right), Y_{2}=W\left(R_{t} \cap D_{2}\right), Y_{3}=W\left(R_{t} \backslash\left(D_{1} \cup D_{2}\right)\right)
$$

Now $Y_{3}$ is independent of $\underset{\underline{H}}{\mathrm{H}}\left(D_{1}\right)$, since

$$
R_{s} \cap\left(R_{t} \backslash\left(D_{1} \cup D_{2}\right)\right)=\varnothing, \quad V s \in D_{1}
$$

and $Y_{1}$ is $\underset{=}{H}\left(D_{1}\right)$-measurable by Lemma 3.5. So

$$
E\left(W_{t} \mid \underset{\underline{H}}{H}\left(D_{1}\right)\right)=W\left(D_{1} \cap R_{\nu}\right)+E\left(Y_{2} \mid \underset{=}{H}\left(D_{1}\right)\right) .
$$

By Lemmas 3.5 and 3.6(a),

$$
E\left(Y_{2} \mid \underset{=}{H}\left(D_{1}\right)\right)=E\left(Y_{2} \mid \underline{\underline{G}}_{i n}^{1} \vee G_{o u v}^{1}\right)=E\left(Y_{2} \mid G_{o u}^{1}\right) .
$$

This concludes the proof of (a). As for (b), it is an immediate consequence of the definitions of $W_{t_{1}}^{1}$ and $\hat{W}$.

### 3.8. Theorem. Set

$$
\underset{=}{K}(\Gamma)=\sigma\left(W_{u}^{1}, 0 \leq u \leq \bar{u}\right) \vee \sigma\left(\int_{[0, \widetilde{u}]} f d \hat{W}, f \text { bounded Borel }\right) .
$$

Then $\underset{=}{\mathrm{K}}(\Gamma)$ is a splitting field for $\underset{=}{\mathrm{H}}\left(\mathrm{D}_{1}\right)$ and $\underset{=}{\mathrm{H}}\left(\overline{\mathrm{D}}_{1}^{c}\right)$ and $\underset{=}{\mathrm{K}}(\Gamma)=\underset{=}{\mathrm{H}}\left(\mathrm{D}_{1}\right) \cap \underset{=}{\mathrm{H}}\left(\overline{\mathrm{D}}_{1}^{c}\right)$ (in particular, $\underset{=}{\mathrm{K}}(\Gamma)$ is the minimal splitting field).

Proof. Proposition 3.1 and 3.4 imply that

$$
\underset{=}{\mathrm{K}}(\Gamma) \subset \underset{=}{\mathrm{H}}\left(\mathrm{D}_{1}\right) \cap \underset{=}{\mathrm{H}}\left(\overline{\mathrm{D}}_{1}^{c}\right) .
$$

To get the converse inclusion, observe that by Lemmas 3.5 and 3.7,

$$
E\left(W_{t} \mid \underset{=}{H}\left(D_{1}\right)\right) \in \underset{=}{K}(\Gamma), \quad V t \in \bar{D}_{1}^{c},
$$

so by the above inclusion,

$$
E\left(W_{t} \mid \underset{=}{H}\left(D_{1}\right)\right)=E\left(W_{t} \mid \underline{=}(\Gamma)\right), \quad V t \in \bar{D}_{1}^{c}
$$

By Lemma 3.6(b), this means that $\underset{=}{\mathrm{K}}(\Gamma)$ is a splitting field for $\underset{=}{\mathrm{H}}\left(\mathrm{D}_{1}\right)$ and $\underset{=}{\mathrm{H}}\left(\overline{\mathrm{D}}_{1}^{\mathrm{c}}\right)$. By (2.1), we get the desired equality.

## 4. Sufficient conditions for equality of the germ and sharp fields.

In this section, we will need the notion of stochastic line integrals for monotone curves. These notions were introduced in [CW; §4] in a more general context.

Suppose $0 \leq a<b$ and $f:[a, b] \rightarrow \mathbf{R}_{+}$is monotone and continuous. Let $\Gamma^{f}=\{(u, f(u)): a \leq u \leq b\}$ be the graph of $f$, which is a continuous monotone curve. Set

$$
W_{u}^{f}=W_{u, f(u)}, W_{u}^{f, 1}=W\left(S_{1}\left(\Gamma_{\mathbf{u}}^{f}\right)\right), W_{u}^{f, 2}=W\left(S_{2}\left(\Gamma_{u}^{f}\right)\right),
$$

where $\Gamma_{u}^{f}=\{(v, f(v)): a \leq v \leq u\}$ and $S_{1}(A)$ (resp. $\left.S_{2}(A)\right)$ denotes the horizontal (resp. vertical) shadow of the set $A$ (see beginning of Section 3). Then ( $W_{u}^{f, i}$, $\mathrm{a} \leq \mathrm{u} \leq \mathrm{b}$ ) is a continuous martingale, $\mathrm{i}=1,2$, with quadratic variation

$$
\left\langle W^{f, 1}\right\rangle_{u}=\int_{a}^{u} f(v) d v,\left\langle W^{f, 2}\right\rangle_{u}=\int_{f(a)}^{f(u)} v d f(v)
$$

When f is non-decreasing, ( $\mathrm{W}_{\mathrm{u}}^{\mathrm{b}}, \mathrm{a} \leq \mathrm{u} \leq \mathrm{b}$ ) is a continuous martingale, and

$$
\left\langle W^{f}\right\rangle_{u}=u f(u)-a f(a)
$$

In this case, if $h \in L^{2}([a, b], d(u f(u)))$, the stochastic line integral of $h$ along $\Gamma^{f}$ is by definition

$$
\int_{\Gamma} h \partial W=\int_{a}^{b} h(u) d W_{u}^{f}
$$

When $f$ is non-increasing, and $h \in L^{2}(f(u) d u) \cap L^{2}(u d f(u))$ is Borel, the stochastic line integral of $h$ along $\Gamma^{f}$ is defined by

$$
\int_{\Gamma} h \partial W=\int_{a}^{b} h(a) d W_{u}^{f, 1}=\int_{a}^{b} h(u) d W_{u}^{f, 2}
$$

Recall that if $f$ is non-decreasing on $[a, b]$, the inverse of $f$ is the function $f^{-1}(v)=\sup \{u: f(u) \leq v\}$, whereas if $f$ is non-increasing, the inverse of $f$ is $f^{-1}(v)=\sup \{u: f(u) \geq v\}$. We also set $\quad \hat{f}^{-1}(v)=\inf \{u: f(u) \geq v\} \quad$ (resp. $\hat{f}^{-1}(v)=\inf \{u: f(u) \leq v\}$ when $f$ is non-decreasing (resp. non-increasing).
4.1. Lemma. Suppose $f:[a, b] \rightarrow \mathbf{R}_{+}$is monotone. Then

$$
\int_{\Gamma^{2}} h \partial W=\int_{\mathbb{R}_{+}^{2}}\left(h\left(S_{1}\right) I_{S_{1}\left(\Gamma^{\eta}\right)}(s)+h\left(f^{-1}\left(S_{2}\right)\right) I_{S_{2}\left(\Gamma^{\prime}\right)}(s)\right) d W_{s}
$$

for all h for which the left-hand side is defined.

Proof. The equality is a simple consequence of the definition of line-integral when $h$ is the indicator function of an interval. The general case follows by a standard Monotone Class argument.
4.2. Lemma. Fix $u_{0} \leq \bar{u}$, and set $f_{1}(u)=L\left(u, u_{0}\right), u \leq u_{0}$, and $f_{2}(u)=L\left(u_{0}, u\right)$, $u_{0} \leq u \leq \bar{u}$. Then for $i=1,2$,
(a) $f_{i}\left(f_{i}^{-1}\left(s_{2}\right)\right)=\phi\left(s_{2}\right)$, and $f_{i}\left(\hat{f}_{i}^{-1}\left(s_{2}\right)\right)=\phi\left(s_{2}\right)$, when $\left(0, s_{2}\right) \in S_{2}\left(\Gamma^{f_{j}}\right)$.
(b) Set $B_{i}=\left\{u: \phi(u)=f_{i}(u)\right\}$. Then $B_{i}^{c}$ is an open set, so we can write

$$
\left.B_{i}^{c}=\bigcup_{k}\right] u_{i}^{k}, v_{i}^{k}[,
$$

where $u_{i}^{k}<v_{i}^{k}$ and the union is countable and disjoint. Then

$$
f_{i}\left(u_{i}^{k}\right)=\phi\left(u_{i}^{k}\right)=\phi\left(v_{i}^{k}\right)=f\left(u_{i}^{k}\right) .
$$

In particular,

$$
\int_{B_{i}^{i}} d f_{i}(u)=0 .
$$

Proof. We only carry out the proof for $B_{1}$, so we drop the index $1: \mathrm{f}(\mathrm{u})=\mathrm{L}\left(\mathrm{u}, \mathrm{u}_{0}\right)$.
(a) By definition, $s_{1}=f^{-1}\left(s_{2}\right)$ satisfies $f\left(s_{1}+\delta\right)<f\left(s_{1}\right)$, V $\delta>0$. Thus

$$
\mathrm{f}\left(\mathrm{~s}_{1}\right)>\max _{\mathrm{s}_{1}+\delta<u<u_{0}} \phi(u) .
$$

Now assume $f\left(s_{1}\right)>\phi\left(s_{1}\right)$. We show that this leads to a contradiction. Indeed, there would be $\varepsilon>0$ and $\delta>0$ such that

$$
s_{1} \leq u \leq s_{1}+\delta \Rightarrow \phi(u)<f\left(s_{1}\right)-\varepsilon .
$$

But then

$$
\mathrm{f}\left(\mathrm{~s}_{1}\right)=\max _{s_{1} \leq u \leq u_{0}} \phi(u)=\max \left(\max _{s_{1} \leq u \leq s_{1}+\delta} \phi(u), \max _{s_{1}+\delta \leq u \leq u_{0}} \phi(u)\right)<\mathrm{f}\left(\mathrm{~s}_{1}\right),
$$

which is the desired contradiction.
(b) Note that $u^{k}$ and $v^{k}$ belong to $B$, so $\phi\left(u^{k}\right)=f\left(u^{k}\right)$ and $\phi\left(v^{k}\right)=f\left(v^{k}\right)$. It remains to check that $f\left(u^{k}\right)=f\left(v^{k}\right)$. Observe that $\phi(u)<f(u), u^{k}<u<v^{k}$, by definition of B. Now suppose $f\left(v^{k}\right)<f\left(u^{k}\right)$. Since $f$ is continuous, there is $\left.w^{k} \in\right] u^{k}, v^{k}\left[\right.$ such that $f\left(u^{k}\right)>f\left(w^{k}\right)>f\left(v^{k}\right)$. But then

$$
\max _{w^{2} s u \leq u_{0}} \phi(u)>\max _{v^{*} \lll u_{0}} \phi(u) .
$$

But since $\phi$ is continuous, there would be $\tilde{u} \in\left[w^{k}, v^{k}\right]$ such that $\phi(\tilde{u})=f\left(w^{k}\right)$. Now

$$
\phi(\tilde{u}) \leq f(\tilde{u}) \leq f\left(w^{b}\right)=\phi(\tilde{u})
$$

so $f(\tilde{u})=\phi(\tilde{u})$, a contradiction since $\tilde{u} \in B^{c}$.
Finally, the last statement holds since

$$
\int_{B^{\mathbf{c}}} d f(u)=\sum_{\mathbf{k}}\left(f\left(\mathbf{v}^{\mathbf{k}}\right)-f\left(u^{k}\right)\right)=0 .
$$

4.3. Lemma. Fix $a<b<u_{0}<\bar{u}$ and set $f_{1}(u)=L\left(u, u_{0}\right)$, $u \leq u_{0}$. Suppose $B \in \underset{=}{B}([a, b])$ satisfies $B \subset B_{1}$ (defined in Lemma 4.2(b)). Then

$$
\int_{\Gamma_{R_{1}}} I_{B} \partial W \in \underset{=}{H}(\Gamma)
$$

(recall that $\left.\Gamma=\{(u, \phi(u))\}, \Gamma^{f_{1}}=\left\{\left(u, f_{1}(u)\right)\right\}\right)$.

Proof. By definition of $B_{1}$, we have $\phi(u)=f_{1}(u), V u \in B$. Since the non-negative measure $f_{1}(u) d u-u d f_{1}(u)$ is outer regular, for each $\varepsilon>0$ there is an open set $U$ such that

$$
\begin{equation*}
B \subset U \text { and } \int_{U}\left(f_{1}(u) d u-\operatorname{udf}_{1}(u)\right) \leq \int_{B}\left(f_{1}(u) d u-u d f_{1}(u)\right)+\varepsilon . \tag{4.1}
\end{equation*}
$$

Now

$$
\left.U=\bigcup_{i} I_{i}, \text { where } I_{i}=\right] u_{i}, v_{i}\left[\text {, and } I_{i} \cap I_{j}=\varnothing, i \neq j\right.
$$

If $B \cap I_{i}=\varnothing$, we simply can remove that $I_{i}$ from the union, without affecting (4.1). So we assume $B \cap I_{i} \neq \varnothing$, for all $i$. Set

$$
a_{i}=\inf \left(B \cap I_{i}\right), b_{i}=\sup \left(B \cap I_{i}\right)
$$

and

$$
V=\bigcup_{i}\left[a_{i}, b_{i}\right]
$$

Then

$$
\begin{equation*}
B \subset V \text { and } \int_{V}\left(f_{1}(u) d u-u d f_{1}(u)\right)<\int_{B}\left(f_{1}(u) d u-u d f_{1}(u)\right)+\varepsilon \tag{4.2}
\end{equation*}
$$

Furthermore,

$$
Y=\int_{\Gamma_{f_{1}}} I_{V} \partial W=\sum_{i}\left(W_{b_{i}, f\left(b_{i}\right)}^{f, 1}-W_{a_{i}, f\left(a_{i}\right)}^{f, 1}\right)-\sum_{i}\left(W_{b_{i}, f\left(b_{i}\right)}^{f, 2}-W_{a_{i}, f\left(a_{i}\right)}^{f, 2}\right)
$$

$$
=\sum_{i}\left(w_{b_{i}, f\left(b_{i}\right)}-W_{a_{i} f\left(L_{i}\right)}\right),
$$

so $Y \in \underset{\left.\underline{H}(T) \text { since } f\left(b_{i}\right)=\phi\left(b_{i}\right) \text { and } f\left(a_{i}\right)=\phi\left(a_{i}\right) \text { (because } a_{i}, b_{i} \in B_{1}\right) \text {. Finally, by }, ~(1)}{ }$ Lemma 4.1 and (4.2),

$$
\left\|\int_{\Gamma_{R_{1}}} I_{V} \partial W-\int_{\Gamma^{1}} I_{B} \partial W\right\|_{L^{2}} \leq \varepsilon .
$$

Since $\varepsilon$ is arbitrary, this completes the proof.
4.4. Lemma. Fix $\bar{u} \geq b>a>u_{0}$ and set $f_{2}(u)=L\left(u_{0}, u\right), u \geq u_{0}$. Suppose $B \in \underset{\underline{B}}{ }([a, b])$ satisfies $B \subset B_{2}$ (defined in Lemma 4.2). Then

$$
\int_{\Gamma^{2}} I_{B} \partial W \in \underset{=}{H}(\Gamma) .
$$

Proof. The proof is similar to that of Lemma 4.3, using the measure $\mathrm{d}(\mathrm{uf}(\mathrm{u}))$. Details are left to the reader.

The following condition will turn out to be sufficient for the equality of the germ and sharp fields of $\Gamma$.
4.5. Assumption. There is a countable dense set Q on $[0, \bar{u}]$ such that for $u_{0} \in Q$, the maps $\mathrm{u} \mapsto \mathrm{L}\left(\mathrm{u}, \mathrm{u}_{0}\right)$ and $\mathrm{u}_{0} \mapsto \mathrm{~L}\left(\mathrm{u}_{0}, \mathrm{u}\right)$ are singular (with respect to Lebesgue measure).
4.6. Lemma. Under Assumption 4.5, the maps $u \mapsto L\left(u, u_{0}\right)$ are singular for all $u \in[0, \bar{u}]$.

Proof. Fix $u_{0} \in[0, \bar{u}]$. To begin "with, if $L\left(0, u_{0}\right)=\phi\left(u_{0}\right)$, then $L\left(\cdot, u_{0}\right)$ is constant on $\left[0, u_{0}\right]$, hence singular. So assume $L\left(0, u_{0}\right)>\phi\left(u_{0}\right)$. Now set

$$
v_{0}=\sup \left\{u \leq u_{0}: L\left(u, u_{0}\right)>\phi\left(u_{0}\right)\right\} .
$$

If $v_{0}<u_{0}$, then $L\left(\cdot, u_{0}\right)$ is constant on $\left[v_{0}, u_{0}\right]$, so it suffices to check that $L\left(\cdot, u_{0}\right)$ is singular on $\left[0, v_{0}\right]$. We may thus assume in addition that $L\left(u, u_{0}\right)>\phi\left(u_{0}\right)$, for all $u<u_{0}$. Then fix $\delta>0$, and let $u_{1} \in\left[u_{0}-\delta, u_{0}\left[\right.\right.$ be such that $\phi\left(u_{1}\right)=L\left(u_{0}-\delta, u_{0}\right)$. Now fix $d_{0} \in\left[u_{1}, u_{0}\right] \cap Q$, where $Q$ is given in 4.5. We claim that

$$
\begin{equation*}
L\left(u, d_{0}\right)=L\left(u, u_{0}\right), \quad V u<u_{0}-\delta . \tag{4.3}
\end{equation*}
$$

Indeed, for $u<u_{0}-\delta, L\left(u, d_{0}\right) \leq L\left(u, u_{0}\right)$ by definition. So suppose
$L\left(u, d_{0}\right)<L\left(u, u_{0}\right)$. Now $L\left(u, d_{0}\right) \geq \phi\left(u_{1}\right)=L\left(u_{0}-\delta, u_{0}\right)$, so if $v \in\left[0, u_{0}\right]$ is such that $\phi(v)=L\left(u, u_{0}\right)$, then $u \leq v<u_{0}-\delta$. Thus $L\left(u, d_{0}\right) \geq \phi(v)=L\left(u, u_{0}\right)$, a contradiction.

By Assumption 4.5 and (4.3), $\mathrm{L}\left(\cdot, u_{0}\right)$ is singular on $\left[0, u_{0}-\delta\right]$, for all $\delta>0$, implying $L\left(\cdot, u_{0}\right)$ is singular on $\left[0, u_{0}\right.$ ]. The proof for $L\left(u_{0}, \cdot\right)$ is similar and is omitted.
4.7. Lemma. Fix $u_{0}, a, b \in\left[0, u_{0}\right]$ such that $a<u_{0}<b$ and $L\left(a, u_{0}\right)=\phi\left(u_{0}\right)=$ $L\left(u_{0}, b\right)$, and define $f_{1}:\left[a, u_{0}\right] \rightarrow \mathbf{R}_{+}$and $f_{2}:\left[u_{0}, b\right] \rightarrow \mathbf{R}_{+}$by $f_{1}(u)=L(a, u)$ and $f_{2}(u)=L(u, b)$. Then under Assumption 4.5, $W\left(S_{1}\left(\Gamma^{f_{i}}\right)\right) \in \underset{=}{\mathrm{H}}(\Gamma)$ and $W\left(S_{2}\left(\Gamma^{f_{i}}\right)\right) \in \underset{=}{\mathrm{H}}(\Gamma), \mathrm{i}=1,2$.

Proof. We only indicate the proof in the case $\mathrm{i}=1$. Let $\mathrm{A}_{1}$ be a set of Lebesgue measure 1 in $\left[\mathrm{a}, \mathrm{u}_{0}\right]$ such that

$$
\int_{A_{1}} \mathrm{df}_{1}(\mathrm{u})=0
$$

Then $A_{2}=B_{1} \cap A_{1}^{c}$ satisfies the hypothesis of Lemma 4.3, so

$$
\begin{aligned}
\int_{\Gamma^{4}} I_{A^{1}} \partial W & =W_{u_{0}, L\left(a, u_{0}\right)}-W_{a, L(a, a)}-\int_{\Gamma^{\prime}} I_{A_{2}} \partial W \\
& \in \stackrel{H}{=}(\Gamma)
\end{aligned}
$$

since $L\left(a, u_{0}\right)=\phi\left(u_{0}\right)$ and $L(a, a)=\phi(a)$. By the change of variables formula of [DM2; chap. VI 2, (55.1)],

$$
\int_{f_{1}(a)}^{f_{1}\left(u_{0}\right)} I_{A_{1}}\left(f_{1}^{-1}\left(s_{2}\right)\right) d s_{2}=\int_{\left[a, u_{0}\right]} I_{A_{1}}(u) d f_{1}(u)=0,
$$

so $\left(s_{1}, s_{2}\right) \mapsto I_{A_{i}}\left(f_{1}^{-1}\left(s_{2}\right)\right)$ is a.s. zero on $S_{2}\left(\Gamma^{f_{1}}\right)$ for $i=1$, and a.s. one for $i=2$. But then Lemma 4.1 implies that

$$
\begin{aligned}
\int_{\Gamma^{f_{1}}} \mathrm{I}_{\mathrm{A}_{1}} \partial \mathrm{~W} & =\int_{\mathbf{R}_{+}^{2}} \mathrm{I}_{\mathrm{A}_{1}}\left(\mathrm{~s}_{1}\right) \mathrm{I}_{\mathrm{s}_{1}\left(\Gamma^{p_{1}}\right)}(\mathrm{s}) \mathrm{dW}{ }_{s} \\
& =W\left(S_{1}\left(\Gamma^{f}\right)\right)
\end{aligned}
$$

since $\left(s_{1}, s_{2}\right) \mapsto I_{A_{1}}\left(s_{1}\right)$ is a.s. the constant function 1 on $S_{1}\left(\Gamma^{f_{1}}\right)$. Similarly,

$$
\int_{\Gamma^{f_{1}}} \mathrm{I}_{\mathrm{B}_{2}} \partial \mathrm{~W}=\mathrm{W}\left(\mathrm{~S}_{2}\left(\Gamma^{\mathrm{f}}\right)\right) .
$$

This completes the proof.
4.8. Proposition. Under Assumption 4.5, $W_{u_{0}}^{i} \in \underset{=}{H}(\Gamma), 0 \leq u_{0} \leq \bar{u}, i=1,2$.

Proof. We begin with the case $i=1$. Fix $n \in N$, and set $x_{j}^{n}=j u_{0} / n, j=0, \ldots, n$. Define $\boldsymbol{g}^{\mathrm{n}}:\left[0, \mathrm{u}_{0}\right] \rightarrow \mathbf{R}$ by

$$
g^{n}(u)=L\left(x_{j}^{n}, x_{j+1}^{n}\right) \text { if } x_{j}^{n}<u \leq x_{j+1}^{n} .
$$

Note that there is $v_{j}^{n} \in\left[x_{j}^{n}, x_{j+1}^{n}\right]$ such that $\left.\left.g^{n}(u)=\phi\left(v_{j}^{n}\right), u \in\right] x_{j}^{n}, x_{j+1}^{n}\right]$.
The map $g^{n}$ is piecewise monotone, though not continuous. Let $0=\mathrm{j}_{0}^{\mathrm{n}}<\mathrm{j}_{1}^{\mathrm{n}}<\cdots<\mathrm{j}_{\mathrm{m}}^{\mathrm{n}}=\mathrm{n}$ be such that $\mathrm{g}^{\mathrm{n}}$ is monotone on $\left[\mathrm{x}_{\mathrm{j},}, \mathrm{x}_{\mathrm{j} \mathrm{l}_{1+1}}\right.$ ] but is not monotone on [ $\mathrm{x}_{\mathrm{j}, \vec{a}}, \mathrm{x}_{\mathrm{j}+1+1}$ ], for each $l$ (it is important to take intervals closed on the left).
 we assume without loss of generality that

$$
\begin{equation*}
\mathrm{g}^{\mathrm{n}} \text { is non-decreasing on }\left[\mathrm{x}_{\mathrm{j}_{0},}, \mathrm{x}_{\mathrm{j}_{\mathrm{l}}}\right] \text {. } \tag{4.4}
\end{equation*}
$$

We then define $\mathrm{h}^{\mathrm{n}}:\left[0, \mathrm{u}_{0}\right] \rightarrow \mathbb{R}$ by

$$
\begin{aligned}
& h^{n}(u)=L\left(v_{j a}, u\right) \text { if } v_{j o} \leq u \leq v_{j \ell_{1}} \text { and } l \text { is even, } \\
& h^{n}(u)=L\left(u, v_{j_{l+1}}\right) \text { if } v_{j l} \leq u \leq v_{j{ }_{j+1}} \text { and } l \text { is odd, } \\
& h^{n}(u)=L\left(v_{j m} u\right) \text { if } v_{j_{m}} \leq u \leq u_{0} .
\end{aligned}
$$

Now $h^{\mathrm{n}}$ is piecewise monotone, and singular by Assumption 4.5, with intervals of monotonicity $\left[0, v_{j_{1}}^{n}\right],\left[v_{j_{1}}^{n}, v_{j_{2}}^{n}\right], \ldots,\left[v_{j_{m-1}}, u_{0}\right]$ and $\phi \leq h^{n} \leq g^{n}$. Since the area of the vertical shadow of $\Gamma^{g^{n}}$ decreases to the area of $D_{u_{0}}^{1}$, the same is true for the area of $S_{1}\left(\Gamma^{h^{2}}\right)$. But then the random variables $W\left(S_{1}\left(\Gamma^{h^{2}}\right)\right.$, which are $\underset{=}{\mathrm{H}}(\Gamma)$-measurable by Lemma 4.7 and Assumption 4.5, converge to $W\left(D_{u_{0}}^{1}\right)$, completing the proof for $i=1$.

To see that $W_{u_{0}}^{2} \in \underset{=}{H}(\Gamma)$, set $k^{n}(u)=\min \left\{h^{n}(v): u \leq v \leq u_{0}\right\}$. Then $k^{n}$ is nondecreasing, and singular since $h^{n}$ is (see proof of Example 4.10(a) below). Furthermore, it is not difficult to see that

$$
\lim _{n \rightarrow \infty} k^{n}(u)=l\left(u, u_{0}\right)
$$

and so

$$
\lim _{n \rightarrow \infty} W\left(S_{2}\left(\Gamma^{k^{n}}\right)\right)=W\left(S_{2}\left(\Gamma^{f_{2}}\right)\right) \text { in } L^{2}(\Omega, \underset{=}{F}, P)
$$

where $f_{2}(u)=l\left(u, u_{0}\right)$. So the proof will be complete if we show that $W\left(S_{2}\left(\Gamma^{k^{\mathbf{k}}}\right)\right) \in$
$\underline{\underline{H}}(\mathrm{~T})$. Since $\mathrm{h}^{\mathrm{n}}$ is piecewise monotone, $\mathrm{k}^{\mathrm{n}}$ will coincide with $\mathrm{h}^{\mathrm{n}}$ on finitely many intervals of the form [ $\mathrm{v}_{\mathrm{j}, \mathrm{h}}, \mathrm{w}_{l}^{\mathrm{n}}$ ], where $l$ will be even (by (4.4)) and

$$
\begin{aligned}
& w_{l}^{n}=\sup \left\{u: v_{j i} \leq u \leq u_{0} \text { and } h^{n}(v)=k^{n}(v), V v \in\left[v_{j,}, u\right]\right\}
\end{aligned}
$$

By Lemma 4.2 (a), we will have

$$
k^{n}\left(w_{l}^{n}\right)=h^{n}\left(w_{l}^{n}\right)=L\left(v_{j}, w_{l}^{n}\right)=\phi\left(w_{l}^{n}\right),
$$

 $f_{l}(u)=h^{n}(u), v_{j i} \leq u \leq w_{l}^{n}$. But then, since $S_{2}\left(\Gamma^{k^{\alpha}}\right)$ is the disjoint union of the $S_{2}\left(\Gamma^{f}\right)$, we get the desired result.
4.9. Theorem. Under Assumption 4.5, $\underset{\underline{\underline{H}}}{(\Gamma)}=\underline{\underline{G}}(\Gamma)$.

Proof. By Proposition 4.8 and Theorem 3.8, we have $\underset{\underline{H}}{ }(\Gamma) \supset \underset{\equiv}{\mathrm{H}}\left(\mathrm{D}_{1}\right) \cap \underset{\underline{\underline{H}}\left(\bar{D}_{1}^{\mathrm{c}}\right) \text {. The }}{ }$ converse inclusion is also clear since $W_{u, \phi(u)} \in \underset{\underline{H}}{H}\left(D_{1}\right) \cap \underline{\underline{H}}\left(\bar{D}_{1}^{\top}\right), 0 \leq u \leq \bar{u}$. So the conclusion follows from Theorem 2.1.

### 4.10. Examples.

(a) If $\phi:[0, \bar{u}] \rightarrow \mathbb{R}_{+}$has bounded variation and is singular with respect to Lebesgue measure, then Assumption 4.5 is satisfied (the converse is also true: see Proposition 6.1).
(b) If $\phi:[0, \bar{u}] \rightarrow \mathbf{R}_{+}$is such that any one of its four Dini derivatives is $+\infty$ a.s. for Lebesgue-measure, then Assumption 4.5 is satisfied. For example,

$$
g(u)=\limsup _{h \neq 0} \frac{\phi(u+h)-\phi(u)}{h}=+\infty \text { a.s. }
$$

implies Assumption 4.5.

Proof. (a) We only check that $u \mapsto f(u)=L\left(u_{0}, u\right)$ is singular. In fact, we prove the stronger statement

$$
\begin{equation*}
\int_{B} d f(u) \leq \int_{B} d|\phi|(u), B \in \mathbb{B}\left(\left[u_{0}, \bar{u}\right]\right) . \tag{4.5}
\end{equation*}
$$

Indeed, assume to begin with that $\mathrm{B}=\mathrm{j}, \mathrm{b} \mathrm{b}$, $\mathrm{a}<\mathrm{b}$. Set

$$
v_{1}=\sup \{u: f(u)=f(a)\}, \quad v_{2}=\inf \{u: f(u)=f(b)\}
$$

If $v_{2} \leq v_{1}$, (4.5) is clearly satisfied. So assume $v_{1}<v_{2}$. Then $f\left(v_{1}\right)<f\left(v_{2}\right)$ and by Lemma $4.2(a), f\left(v_{1}\right)=\phi\left(v_{1}\right)$ and $f\left(v_{2}\right)=\phi\left(v_{2}\right)$. Thus

$$
\int_{] a, b]} d f(u)=f\left(v_{2}\right)-f\left(v_{1}\right)=\phi\left(v_{2}\right)-\phi\left(v_{1}\right) \leq \int_{[a, b]} d|\phi|(u),
$$

and so (4.3) holds in this special case and also if B is a countable union of intervals. The general case follows since any Borel set can be approximated from above in $d f(u)+d|\phi|(u)$-measure by a countable union of intervals.
(b) Fix $u_{0} \in[0, \bar{u}]$. For any $u \leq u_{0}$, such that $g(u)=+\infty$, we have $\mathrm{L}\left(\mathrm{u}, \mathrm{u}_{0}\right)>\phi(\mathrm{u})$. So by Lemma 4.2 (b),

$$
\int_{\{u: g(u)=\infty\} \cap\left[0, u_{0}\right]} L\left(d u, u_{0}\right)=0 .
$$

But since by hypothesis, $\{\mathrm{v}: \mathrm{g}(\mathrm{v})=\infty\} \cap\left[0, \mathrm{u}_{0}\right]$ has Lebesgue-measure $\mathrm{u}_{0}$, $\mathbf{u} \mapsto \mathrm{L}\left(\mathrm{u}_{0}, \mathrm{u}\right)$ is singular.

We now check that $u \mapsto L\left(u_{0}, u\right)$ is singular. Indeed, $u \mapsto L\left(u_{0}, u\right)$ has a Lebesgue-decomposition

$$
L\left(u_{0}, u\right)=\int_{u_{0}}^{u} h(v) d v+v(u),
$$

where $v(\cdot)$ is a non-decreasing singular function and $h$ is non-negative and integrable on [ $u_{0}, u$ ]. Thus

$$
\begin{equation*}
\frac{\partial}{\partial u} L\left(u_{0}, u\right)=h(u) \text { a.s. } \tag{4.6}
\end{equation*}
$$

with respect to Lebesgue-measure. However, at every point $u$ in the support of $v \mapsto L\left(u_{0}, v\right), L\left(u_{0}, u\right)=\phi(u)$, so for du-almost all $u$ in the support, $h(u)=g(u)=+\infty$. Since $h$ is integrable the support of $v \mapsto L\left(u_{0}, v\right)$ must be a Lebesgue-null set, concluding the proof.
4.11. Remark. Theorem 4.9 remains valid if Assumption 4.5 is replaced by an analogous assumption on the functions $l\left(\cdot, u_{0}\right)$ and $l\left(u_{0}, \cdot\right), 0 \leq u_{0}<\bar{u}$.

- Theorem 4.9 also remains valid if Assumption 4.5 is replaced by either of the following two assumptions:

$$
\mathrm{L}\left(\cdot, \mathrm{u}_{0}\right) \text { and } l\left(\cdot, \mathrm{u}_{0}\right) \text { are singular, } \mathrm{Vu}_{0} \in \mathrm{D}
$$

or

$$
\mathrm{L}\left(u_{0}, \cdot\right) \text { and } l\left(u_{0}, \cdot\right) \text { are singular, } V u_{0} \in \mathrm{D}
$$

(recall that D is a countable dense set). The important feature in each of these assumptions is that we have both non-increasing and non-decreasing functions in each case.

- Assumption 4.5 does not imply that $u \mapsto l(0, u)$ is singular, as shown by the example below.
4.12. Example. We are going to define a function $\phi:[0,1] \rightarrow \mathbf{R}_{+}$which is continuous, satisfies Assumption 4.5, but for which $l(0, \cdot)$ is absolutely continuous with respect to Lebesgue-measure. Let $\mathrm{f}:[0,1] \rightarrow \mathbf{R}$ be a continuous function which has the following properties:

$$
\begin{aligned}
& -f(0)=f(1)=0 \\
& -f(u)>0,0<u<1 \\
& -\limsup _{h \rightarrow 0} \frac{f(u+h)-f(u)}{h}=+\infty, \text { for almost all } u \in[0,1] \\
& -\max \{f(u): 0 \leq u \leq 1\}=1 .
\end{aligned}
$$

Let $C$ be a Cantor set, obtained by removing from [0,1] at the $k^{\text {th }}$ step $2^{k-1}$ open intervals $I_{k_{1}, 1}, \ldots, I_{k_{2} 2^{k-1}}$ of length $4^{-k}$. Then $C$ has Lebesgue measure $1 / 2$. Let $\left.I_{k, j}=\right] u_{k_{k j}} v_{k, j}[$. We then set

$$
\begin{array}{ll}
\phi_{1}(u)=2^{-k / 2} f\left(\left(u-u_{k, j}\right) 4^{k}\right), & u_{k, j} \leq u \leq v_{k, j}, \\
\phi_{1}(u)=0 & , u \in C .
\end{array}
$$

Observe that $\phi_{1}$ is continuous on $[0,1]$, and for all $u \in C$,

$$
\limsup _{h \downarrow 0} \frac{\phi_{1}(u+h)-\phi_{1}(u)}{h}=+\infty .
$$

Finally, we set

$$
\phi(u)=1 / 2-\int_{0}^{u} I_{C}(v) d v+\phi_{1}(x)
$$

It is then clear that $\phi$ satisfies the condition of Example 4.10 (b), and so Assumption 4.5 is valid. On the other hand, it is easy to see that

$$
l(0, \mathrm{u})=\frac{1}{2}-\int_{0}^{\mathrm{u}} \mathrm{I}_{\mathrm{C}}(\mathrm{v}) \mathrm{dv},
$$

so $l(0, \cdot)$ is absolutely continuous with respect to Lebesgue-measure.
4.13. Corollary. Let $C=\left\{f: \mathbf{R}_{+} \rightarrow \mathbf{R}: f(0)=1\right.$ and $f$ is continuous $\}$, and let $B$ denote Wiener measure on $C$. For $f \in C$, set

$$
\begin{array}{ll}
\zeta(\mathrm{f})= & \inf \{\mathrm{u}>0: \mathrm{f}(\mathrm{u})=0\} \\
\zeta(\mathrm{f}) & \{\quad\} \neq \varnothing, \\
\text { otherwise } .
\end{array}
$$

Let $\phi(f)$ be the restriction of $f$ to $[0, \zeta(f)]$. Then

$$
\mathrm{B}\left\{\mathrm{f} \in \mathrm{C}: \zeta(\mathrm{f})<+\infty \text { and } \underset{\underline{H}}{\mathrm{H}}\left(\Gamma^{\phi(\mathrm{f})}\right)=\mathrm{G}\left(\Gamma^{\phi(\mathrm{f})}\right)\right\}=1 .
$$

Proof. Immediate consequence of Example 4.10 (b) and Theorem 4.9.

## 5. Some necessary conditions for equality of the germ and sharp fields.

In Theorem 3.8, we determined the generators of the minimal splitting field for $\underset{\underline{H}}{ }\left(\mathrm{D}_{1}\right)$ and $\underset{\underline{H}}{\mathrm{H}}\left(\overline{\mathrm{D}}_{1}^{\mathrm{c}}\right)$. By Theorem 2.1, these are the generators of the germ field. In this section, we are going to give an explicit integral representation for the closed Gaussian linear subspace spanned by these generators. By Theorem 2.1, this subspace is $G(T)$.

These results generalize those of [DR; Th. 3.8], where such a representation is given when $\phi$ is decreasing. Also Rozanov [R; Chap. 3; Sect. 3.5] has given an implicit representation of $\mathbf{G}(\Gamma)$ in terms of the solution to a generalized partial differential equation, when $\Gamma$ is the boundary of any bounded open set. Our representation can thus be viewed as the solution to Rozanov's equation when $\Gamma$ is the graph of a continuous function $\phi$.

Once we have a good description of $G(\Gamma)$ at our disposal, it becomes possible, under a rather weak regularity assumption on $\phi$, to give conditions under which an element of $G(\Gamma)$ does not belong to $H(\Gamma)$. Though we do not give a complete description of $\mathrm{H}(\Gamma)$ (and such a description is unnecessary for our purposes), this approach leads to necessary and sufficient conditions on $\phi$ for equality of the germ and sharp fields (provided $\phi$ satisfies Assumption 5.6 below). In particular, when $\phi$ has bounded variation, Corollary 5.15 gives a complete answer to the question: " when are $\underset{=}{F}(\Gamma)$ and $\underset{\underline{G}(\Gamma) \text { equal?' }}{ }$

If $f_{1}, f_{2}:[0, \bar{u}] \rightarrow \mathbf{R}$ are two Borel functions, we define three Borel functions $J_{1}\left(f_{1}, f_{2}\right), J_{2}\left(f_{1}, f_{2}\right)$ and $J\left(f_{1}, f_{2}\right)$ on $T$ by

$$
\begin{aligned}
J_{1}\left(f_{1}, f_{2}\right)(t) & =\left(f_{1}\left(t_{1}\right)+f_{2}(p(t))\right) I_{D_{1}}(t) \\
J_{2}\left(f_{1}, f_{2}\right)(t) & =f_{2}(p(t)) I_{D_{2}}(t) \\
J\left(f_{1}, f_{2}\right)(t) & =J_{1}\left(f_{1}, f_{2}\right)(t)+J_{2}\left(f_{1}, f_{2}\right)(t) .
\end{aligned}
$$

5.1. Lemma. (a) Suppose $J\left(f_{1}, f_{2}\right) \in L^{2}(T, d t)$. Then $J_{i}\left(f_{1}, f_{2}\right) \in L^{2}(T, d t), i=1,2$. In particular, $\mathrm{f}_{2} \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{2}\right)} \in \mathrm{L}^{2}\left([0, \bar{u}], \mathrm{d} \mu_{2}\right)$.
(b) Suppose ( $\mathrm{f}_{1}^{\mathrm{n}}, \mathrm{n} \in \mathbb{N}$ ) and ( $\mathrm{f}_{2}^{\mathrm{n}}, \mathrm{n} \in \mathbb{N}$ ) are sequences of Borel functions such that $J\left(\mathrm{f}_{1}^{\mathrm{n}}, \mathrm{f}_{2}^{\mathrm{n}}\right) \in \mathrm{L}^{2}(\mathrm{~T}, \mathrm{dt})$ for all $\mathrm{n} \in \mathbb{N}$ and

$$
\mathrm{g}=\lim _{\mathrm{n} \rightarrow \infty} \mathrm{~J}\left(\mathrm{f}_{1}^{\mathrm{n}}, \mathrm{f}_{2}^{\mathrm{n}}\right)
$$

exists in $L^{2}(T, d t)$. Then

$$
\mathrm{g}_{\mathrm{i}}=\lim _{\mathrm{n} \rightarrow \infty} \mathrm{~J}_{\mathrm{i}}\left(\mathrm{f}_{1}^{\mathrm{n}}, \mathrm{f}_{2}^{\mathrm{n}}\right)
$$

exists in $L^{2}(T, d t), i=1,2$. In addition, there is a Borel function $f_{2}:[0, \bar{u}] \rightarrow \mathbf{R}$ such that

$$
\mathrm{f}_{2} \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{2}\right)}=\lim _{\mathrm{n} \rightarrow \infty} \mathrm{f}_{2}^{\mathrm{n}} \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{2}\right)} \text { in } \mathrm{L}^{2}\left([0, \overline{\mathrm{u}}], \mathrm{d} \mu_{2}\right)
$$

and $g_{2}(t)=f_{2}(p(t)) d t-$.s. (Note: the question of convergence of $f_{2}^{n} \mathrm{I}_{p\left(D_{1}\right)}$ is addressed in Lemma 5.2).

Proof. (a) Let $\|\cdot\|$ denote the norm in $L^{2}(T, d t)$. Since $J_{1}\left(f_{1}, f_{2}\right)(t) J_{2}\left(f_{1}, f_{2}\right)(t)=0, \quad V t \in T$, we have

$$
\begin{equation*}
\left\|J\left(f_{1}, f_{2}\right)\right\|^{2}=\left\|J_{1}\left(f_{1}, f_{2}\right)\right\|^{2}+\left\|J_{2}\left(f_{1}, f_{2}\right)\right\|^{2} \tag{5.1}
\end{equation*}
$$

This implies the first statement in (a). The second is a consequence of the relation

$$
\begin{equation*}
\int_{[0, \mathrm{u}]}\left(\mathrm{f}_{2}(\mathrm{u})\right)^{2} \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{2}\right)}(\mathrm{u}) \mathrm{d} \mu_{2}(\mathrm{u})=\int_{\mathbf{R}_{+}^{2}}\left(\mathrm{~J}_{2}\left(\mathrm{f}_{1}, \mathrm{f}_{2}\right)(\mathrm{t})\right)^{2} \mathrm{dt} . \tag{5.2}
\end{equation*}
$$

(b) If ( $\mathrm{J}\left(\mathrm{f}_{1}^{\mathrm{n}}, \mathrm{f}_{2}^{\mathrm{n}}\right.$ ), $\mathrm{n} \in \mathbb{N}$ ) is a Cauchy sequency in $\mathrm{L}^{2}(\mathrm{~T}, \mathrm{dt})$, then (5.1) implies that ( $\mathrm{J}_{\mathrm{i}}\left(\mathrm{f}_{1}^{\mathrm{n}}, \mathrm{f}_{2}^{\mathrm{n}}\right), \mathrm{n} \in \mathbb{N}$ ) is also, $\mathrm{i}=1,2$. This yields the first statement of (b). To get the second statement, observe by (5.2) that $\left(\mathrm{f}_{2}^{\mathrm{n}} \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{2}\right)}, \mathrm{n} \in \mathbb{N}\right)$ converges in $\left.L^{2}([0, \bar{u}]), d \mu_{2}\right)$. Choose a Borel function $f_{2}$ which is a $\mu_{2}$-version of this limit. Then

$$
\begin{aligned}
&\left\|g_{2}-\left(f_{2} \circ p\right) I_{D_{2}}\right\| \leq\left\|g-J_{2}\left(f_{1}^{n}, f_{2}^{n}\right)\right\| \\
&+\left\|J_{2}\left(f_{1}^{n}, f_{2}^{n}\right)-\left(f_{2}^{n} \circ p\right) I_{D_{2}}\right\|+\left\|\left(f^{n} \circ p\right) I_{D_{2}}-\left(f_{2} \circ p\right) I_{D_{2}}\right\| \\
&=\left\|g-J_{2}\left(f_{1}^{n}, f_{2}^{n}\right)\right\|+\left\|f_{2}^{n} \mathrm{I}_{p\left(D_{2}\right)}-f_{2}\right\|_{L^{2}\left(d \mu_{2}\right)} \\
& \rightarrow 0
\end{aligned}
$$

as $\mathrm{n} \rightarrow \infty$.

Set

$$
L_{1}=\bigcap_{\infty 0} L^{2}\left([0, \bar{u}-\varepsilon], d \mu_{1}\right], L_{2}=\bigcap_{\varepsilon>0} L^{2}\left([0, \bar{u}-\varepsilon], d \mu_{2}\right)
$$

If $g \in L^{2}(T, d t)$ satisfies $g=J_{1}\left(f_{1}, f_{2}\right)$ for some couple $\left(f_{1}, f_{2}\right) \in L_{1} \times L_{2}$, we say that $g$ is determined by $\left(f_{1}, f_{2}\right)$. If $k \in \mathbf{R}$, and we set

$$
f_{1}^{k}=f_{1}-k, f_{2}^{k}=\left(f_{2}+k\right) I_{p\left(D_{1}\right)}+f_{2} L_{p\left(D_{1}^{\prime}\right)}
$$

then $\left(f_{1}^{k}, f_{2}^{k}\right)$ also determines $g$.
Now fix $s^{0}=\left(s_{1}^{0}, s_{2}^{0}\right) \in D_{1}$ such that $R_{s^{0}} \subset D_{1}$ (recall that $R_{s^{0}}=\left\{s \in \mathbb{R}_{+}^{2}: s_{1} \leq s_{1}^{0}\right.$ and $\left.s_{2} \leq s_{2}^{0}\right\}$ ). For any $g \in L^{2}(T, d t)$ which is determined by some ( $f_{1}, f_{2}$ ), we may (by adding an appropriate constant to $f_{1}$ ) choose ( $\tilde{f}_{1}, \tilde{f}_{2}$ ) that determines $g$ and such that

$$
\begin{equation*}
\int_{0}^{s_{1}^{0}} \tilde{\mathrm{f}}_{1}(\mathrm{u}) \mathrm{du}=0 \tag{5.3}
\end{equation*}
$$

Finally, for $\varepsilon>0$, set $\tau_{\varepsilon}=\inf \{u: \phi(u)=\varepsilon\}$ and $D_{\varepsilon}^{1}=\left\{\left(s_{1}, s_{2}\right) \in D^{1}: s_{1}<\tau^{\varepsilon}\right\}$.

### 5.2. Lemma.

(a) If $\left(f_{1}, f_{2}\right) \in L_{1} \times L_{2}, \quad$ then for each $\varepsilon>0, \quad t \mapsto f_{1}\left(t_{1}\right) I_{D_{e}^{1}}$ and $t \mapsto\left(f_{2} \circ p\right)(t) I_{\left[0, \tau_{e}\right]}(p(t))$ belong to $L^{2}(T, d t)$.
(b) If $J_{1}\left(f_{1}, f_{2}\right) \in L^{2}(T, d t)$, then $\left(f_{1}, f_{2}\right) \in L_{1} \times L_{2}$.
(c) Suppose $g \in L^{2}(T, d t)$ is determined by $\left(f_{1}, f_{2}\right) \in L_{1} \times L_{2}$ where $f_{1}$ satisfies (5.3). Then for each $\varepsilon>0$, there are constants $K_{1}^{\varepsilon}$ and $K_{2}^{\varepsilon}$ such that

$$
\begin{aligned}
& \left\|\mathrm{f}_{1} \mathrm{I}_{\left[0, \tau_{e}\right]}\right\|_{L^{2}\left([0, \bar{u}], d \mu_{1}\right)} \leq \mathrm{K}_{1}^{\varepsilon}\|\mathrm{g}\|, \\
& \left\|\mathrm{f}_{2} \mathrm{I}_{\left[0, \tau_{e}\right]}\right\|_{L^{2}\left([0, \bar{u}], d \mu_{2}\right)} \leq \mathrm{K}_{2}^{\varepsilon}\|\mathrm{g}\| .
\end{aligned}
$$

(d) Suppose $\left(g^{n}, n \in \mathbb{N}\right)$ is a sequence in $L^{2}\left(R_{+}^{2}, d t\right)$ converging io $g$. If $g^{n}$ is determined by $\left(\mathrm{f}_{1}^{\mathrm{n}}, \mathrm{f}_{2}^{\mathrm{n}}\right) \in \mathrm{L}_{1} \times \mathrm{L}_{2}$, where $\mathrm{f}_{1}^{\mathrm{n}}$ satisfies (5.3), then there is $\left(\mathrm{f}_{1}, \mathrm{f}_{2}\right) \in \mathrm{L}_{1} \times \mathrm{L}_{2}$ that determines g , and for each $\varepsilon>0$,

$$
\begin{aligned}
\mathrm{f}_{1} \mathrm{I}_{\left[0, \tau_{e}\right]} & =\lim _{n \rightarrow \infty} \mathrm{f}_{1}^{n} \mathrm{I}_{\left[0, \tau_{e}\right]} \text { in } \mathrm{L}^{2}\left([0, \overline{\mathrm{u}}], \mathrm{d} \mu_{1}\right), \\
\mathrm{f}_{2} \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{1}\right) \cap\left[0, \tau_{e}\right]} & =\lim _{\mathrm{n} \rightarrow \infty} \mathrm{f}_{2}^{n} \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{1}\right) \cap\left[0, \tau_{e}\right]} \text { in } L^{2}\left([0, \bar{u}], \mathrm{d} \mu_{2}\right),
\end{aligned}
$$

Proof. (a) Observe that

$$
\int_{T}\left(f_{1}\left(t_{1}\right)\right)^{2} I_{D_{e}^{1}}(t) d t=\int_{0}^{\tau_{e}}\left(f_{1}(u)\right)^{2} \phi(u) d u \leq L(0, \bar{u}) \int_{0}^{\tau_{e}}\left(f_{1}(u)\right)^{2} d \mu_{1},
$$

and

$$
\int_{T}\left(\left(f_{2} \circ p\right)(t)\right)^{2} I_{\left[0, \tau_{e}\right]}(p(t)) d t=\int_{0}^{\tau_{e}}\left(f_{2}(u)\right)^{2} d \mu_{2}(u)
$$

so the conclusion follows by definition of $L_{1}$ and $L_{2}$ and the fact that $\tau_{\varepsilon}<\bar{u}$.
(b) Suppose $J_{1}\left(f_{1}, f_{2}\right) \in L^{2}(T, d t)$. Then $J_{1}\left(f_{1}, f_{2}\right) \in L^{2}\left(R_{s}, d t\right)$. Since $p\left(t_{1}, t_{2}\right)=p\left(0, t_{2}\right)$, for all $t \in R_{s} 0$, we get

$$
\int_{0}^{s_{1}^{0}} d t_{1} \int_{0}^{s_{2}^{0}} d t_{2}\left(f_{1}\left(t_{1}\right)+f_{2}\left(p\left(0, t_{2}\right)\right)\right)^{2}<\infty .
$$

By Fubini's theorem, this implies that for almost-all $t_{1}$,

$$
\mathrm{t}_{2} \mapsto \mathrm{f}_{1}\left(\mathrm{t}_{1}\right)+\mathrm{f}_{2}\left(\mathrm{p}\left(0, \mathrm{t}_{2}\right)\right)
$$

belongs to $L^{2}\left(\left[0, s_{2}^{0}\right], d_{2}\right)$. But then $t_{2} \mapsto f_{2}\left(p\left(0, t_{2}\right)\right)$ also belongs to $L^{2}\left(\left[0, s_{2}^{0}\right], d_{2}\right)$, which, when $\varepsilon<\mathrm{s}_{2}^{0}$, implies in particular that

$$
\int_{0}^{\tau_{e}} \mathrm{dt}_{1} \int_{0}^{\varepsilon} \mathrm{dt}_{2}\left(\mathrm{f}_{2}(\mathrm{p}(\mathrm{t}))\right)^{2}=\tau_{\varepsilon} \int_{0}^{\varepsilon} d t_{2}\left(f_{2}\left(p\left(0, t_{2}\right)\right)\right)^{2}<+\infty .
$$

But then $t \mapsto f_{2}(p(t))$ belongs to $L^{2}\left(\left[0, \tau_{\varepsilon}\right] \times[0, \varepsilon], d t\right)$, and since

$$
\begin{equation*}
J_{1}\left(f_{1}, f_{2}\right)(t)=\left(f_{1}\left(t_{1}\right)+f_{2}(p(t)) I_{D^{1}}(t),\right. \tag{5.4}
\end{equation*}
$$

we get that

$$
\begin{equation*}
\int_{0}^{\tau_{\varepsilon}} d t_{1} \int_{0}^{\varepsilon} d t_{2}\left(f_{1}\left(t_{1}\right)\right)^{2}<+\infty . \tag{5.5}
\end{equation*}
$$

But then

$$
\varepsilon \int_{0}^{\tau_{\varepsilon}} \mathrm{dt}_{1}\left(\mathrm{f}_{1}\left(\mathrm{t}_{1}\right)\right)^{2}<+\infty,
$$

so $f_{1} \in L^{2}\left(\left[0, \tau_{\varepsilon}\right], d \mu_{1}\right)$. Since $\varepsilon$ is arbitrary, $f_{1} \in L_{1}$.
On the other hand, (5.5) implies

$$
\int_{0}^{\tau_{e}} \mathrm{dt}_{1} \int_{0}^{\phi\left(t_{1}\right)} \mathrm{dt}_{2}\left(\mathrm{f}_{1}\left(\mathrm{t}_{1}\right)\right)^{2} \leq \frac{\mathrm{L}(0, \overline{\mathrm{u}})}{\varepsilon} \int_{0}^{\tau_{\varepsilon}} d t_{1} \int_{0}^{\varepsilon} d t_{2}\left(f_{1}\left(\mathrm{t}_{1}\right)\right)^{2}<+\infty,
$$

so $t \mapsto f_{1}\left(t_{1}\right) I_{D_{\tau_{e}}^{1}}$ belongs to $L^{2}(T, d t)$. But then (5.4) implies that $t \mapsto f_{2}(p(t)) I_{D_{\varepsilon_{e}}^{1}}$ belongs to $L^{2}(T, d t)$. By the definition of $\mu_{2}$, we find that $f_{2} \in L^{2}\left(\left[0, \tau_{\varepsilon}\right], d \mu_{2}\right)$. Since $\varepsilon$ is arbitrary, $\mathrm{f}_{2} \in \mathrm{~L}_{2}$, concluding the proof of (b).
(c) Set $\tilde{f}_{1}(t)=f_{1}\left(t_{1}\right), t=\left(t_{1}, t_{2}\right)$, and fix $r>0$ such that $r<s_{2}^{0}$. We have

$$
\begin{aligned}
+\infty & >\|g\|^{2} \geq \int_{0}^{s_{1}^{0}} d t_{1} \int_{r}^{s_{2}^{0}} d t_{2} g^{2}(t) d t \\
& =\left(s_{2}^{0}-r\right) \int_{0}^{s_{1}^{0}}\left(f_{1}\left(t_{1}\right)\right)^{2} d t_{1}+2 \int_{0}^{s_{1}^{0}} d t_{1} f_{1}\left(t_{1}\right) \int_{r}^{s_{2}^{0}} d t_{2} f_{2}(p(t))+s_{1}^{0} \int_{r}^{s_{2}^{0}}\left(f_{2}(s(t))\right)^{2} d t_{2}
\end{aligned}
$$

(we have used the fact that on $R_{s} 0, f_{2} \circ p$ is a function of $t_{2}$ only. The use of $r>0$ is necessary to write the double product as an iterated integral). By (5.3), the second term in the last equality above is zero, and so, letting $r$ go to zero in (5.6), we get

$$
\begin{equation*}
\left\|\tilde{\mathrm{f}}_{1} \mathrm{I}_{\mathrm{R}_{0}}\right\| \leq\|\mathrm{g}\|,\left\|\left(\mathrm{f}_{2} \circ \mathrm{p}\right) \mathrm{I}_{\mathrm{R}_{0}}\right\| \leq\|\mathrm{g}\| . \tag{5.7}
\end{equation*}
$$

We are now going to use several times the fact that $g=\tilde{f}_{1}+f_{2} \circ p$ on $D^{1}$, and $\tilde{f}_{1}$ only depends on $t_{1}$ and $f_{2} \circ p$ only depends on $p(t)$. We have

$$
\begin{aligned}
\int_{R_{0}}\left(f_{2}(p(t))\right)^{2} d t & =\int_{0}^{s_{2}^{0}} d t_{2} \int_{0}^{s_{1}^{0}} d t_{1}\left(f_{2}(p(t))\right)^{2} \\
& =\int_{0}^{s_{2}^{0}} d t_{2}\left(f_{2}(p(t))\right)^{2} s_{1}^{0} \\
& \geq \frac{s_{1}^{0}}{\bar{u}} \int_{0}^{s_{2}^{0}} d t_{2}\left(f_{2}(s(t))\right)^{2} \int_{0}^{p\left(0, t_{2}\right)} d t_{1} \\
& =\frac{s_{1}^{0}}{\bar{u}} \int_{p^{-1}\left(p\left(R_{0}\right)\right)}\left(f_{2}(p(t))\right)^{2} d t
\end{aligned}
$$

so by (5.7),

$$
\left\|\left(f_{2} \circ p\right){\underset{\mathrm{L}}{\mathrm{p}^{-1}}\left(\mathrm{p}\left(\mathrm{R}_{0},\right)\right) \| \leq \frac{\overline{\mathrm{u}}}{}}_{\mathrm{s}_{1}^{0}}\right\| \mathrm{g} \| .
$$

For $0<\varepsilon<s_{2}^{0}$, this inequality implies

$$
\begin{aligned}
\left\|\tilde{f}_{1} \mathrm{I}_{\left[0, \tau_{e}\right] \times[0, \varepsilon]}\right\| & \leq\left\|\tilde{f}_{1} \mathrm{~L}_{\left.\mathrm{p}^{-1}\left(\mathrm{p}\left(\mathrm{R}_{0}\right)\right)\right)}\right\|=\left\|\left(\mathrm{g}-\left(\mathrm{f}_{2} \circ \mathrm{p}\right)\right) \mathrm{L}_{\left.\mathrm{p}^{-1}\left(\mathrm{p}\left(\mathrm{R}_{\mathrm{p}}\right)\right)\right)}\right\| \\
& \leq\left(1+\frac{\overline{\mathrm{u}}}{\mathrm{~s}_{1}^{0}}\right)\|\mathrm{g}\|
\end{aligned}
$$

Now since $\tilde{f}_{1}$ depends only on $t_{1}$, we get

$$
\left\|\tilde{\mathrm{f}}_{1} \mathrm{I}_{\mathrm{D}_{\mathrm{e}}^{1}}\right\| \leq \frac{\mathrm{L}(0, \overline{\mathrm{u}})}{\varepsilon}\left\|\tilde{\mathrm{f}}_{1} \mathrm{I}_{\left[0, \tau_{\varepsilon}\right] \times[0, \varepsilon]}\right\|
$$

so for some constant $\tilde{K}_{1}^{\varepsilon}$,

$$
\begin{equation*}
\left\|\tilde{f}_{1} I_{D_{e^{1}}}\right\| \leq \tilde{\mathrm{K}}_{1}^{\varepsilon}\|\mathrm{g}\| . \tag{5.8}
\end{equation*}
$$

If we now set $K_{2}^{\varepsilon}=1+\tilde{K}_{1}^{\varepsilon}$, we get

$$
\begin{equation*}
\left\|\left(\mathrm{f}_{2} \circ \mathrm{p}\right) \mathrm{I}_{\mathrm{D}_{\mathrm{e}}^{1}}\right\| \leq \mathrm{K}_{2}^{\varepsilon}\|\mathrm{g}\| . \tag{5.9}
\end{equation*}
$$

Finally, observe that (5.8) implies

$$
\begin{equation*}
\left\|\mathrm{f}_{1} \mathrm{I}_{\left[0, \tau_{e}\right]}\right\|_{\mathrm{L}^{2}\left([0, \tilde{\mathrm{u}}], d \mu_{1}\right)} \leq \frac{1}{\varepsilon}\left\|\tilde{f}_{1} \mathrm{I}_{\mathrm{D}_{\mathrm{e}}}\right\| \leq \mathrm{K}_{1}^{\varepsilon}\|\mathrm{g}\| \tag{5.10}
\end{equation*}
$$

for an appropriate constant $K_{1}^{\varepsilon}$, and (5.9) implies

$$
\begin{equation*}
\left\|f_{2} \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{1}\right) \cap\left[0, ₹_{z}\right]}\right\|_{\mathrm{L}^{2}\left((0, \overline{\mathrm{u}}], \mathrm{d} \psi_{2}\right)} \leq\left\|\left(\mathrm{f}_{2} \circ \mathrm{p}\right) \mathrm{I}_{\mathrm{D}_{\varepsilon}^{1}}\right\| \leq \mathrm{K}_{2}^{\varepsilon}\|\mathrm{g}\| . \tag{5.11}
\end{equation*}
$$

(d) If $\varepsilon \leq \varepsilon^{\prime}$, then $\tau_{\varepsilon} \geq \tau_{\varepsilon^{\prime}}$. Furthermore, $\quad \lim _{\varepsilon \rightarrow 0} \tau_{\varepsilon}=\bar{u} . \quad$ By (5.10), ( $f_{1}^{n} I_{\left[0, \tau_{1 k}\right]}, n \in \mathbf{N}$ ) converges in $L^{2}\left([0, \bar{u}], d \mu_{1}\right)$. Fix $k_{0} \in \mathbb{N}$ large enough, and let $h_{1}^{k}$ be a Borel function which is a version of the limit of this sequence, and define $f_{1}$ : $[0, \bar{u}] \rightarrow \mathbb{R}$ by

$$
f_{1}(u)= \begin{cases}h_{1}^{k_{0}}(u) & \text { if } u \leq k_{0}, \\ h_{1}^{k+1}(u) & \text { if } \tau_{1 / k}<u \leq \tau_{1 /(k+1)} \\ 0 & \text { if } u=\bar{u}\end{cases}
$$

Then $f_{1}$ is Borel, and

$$
\mathrm{f}_{1} \mathrm{I}_{\left[0, \tau_{1 k}\right]}=\mathrm{f}_{1}^{\mathrm{k}} \mathrm{I}_{\left[0, \tau_{1 k}\right]} \mu_{1} \text {-a.s. }
$$

In a similar fashion, we get from inequality (5.11) a Borel function $\mathrm{f}_{2}:[0, \overline{\mathrm{u}}] \rightarrow \mathbb{R}$ such that for each $k \geq k_{0}$,

$$
\mathrm{f}_{2} \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{1}\right) \cap\left[0, \tau_{1 k}\right]}=\lim _{\mathrm{n} \rightarrow \infty} \mathrm{f}_{2}^{\mathrm{n}} \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{1}\right) \cap\left[0, \tau_{1 k}\right]} \text { in } \mathrm{L}^{2}\left([0, \overline{\mathrm{u}}], \mathrm{d} \mu_{2}\right)
$$

It only remains to be shown that $\left(f_{1}, f_{2}\right)$ determines $g$ (note that $f_{1}$ satisfies (5.3)). This follows from the equality

$$
\left\|\left(g-J_{1}\left(f_{1}, f_{2}\right)\right) I_{D_{e}^{2} \cap\left(\left[0, \tau_{e}\right] \times(\varepsilon, \infty)\right.}\right\|=0, \quad V \varepsilon>0,
$$

which is valid by the definition of $f_{1}$ and $f_{2}$.
5.3. Remark. It is not possible to remove the $\mathrm{I}_{\mathrm{D}_{e}^{1}}$ or the $\mathrm{I}_{\left[0, \tau_{e}\right]}$ in the statements of Lemma 5.2, as the following example shows. Consider the continuous function $\phi:[0,1] \rightarrow \mathbf{R}_{+}$which is obtained by modifying the function $\tilde{\phi}(u)=1-u$ on each interval $\left[1-2^{-n+1}, 1-2^{-n}\right.$ ] as follows: $\phi$ is linear on each of the intervals

$$
\begin{aligned}
& I_{n}^{1}=\left[1-2^{-n+1}, 1-72^{-n+1} / 8\right] \\
& I_{n}^{2}=\left[1-72^{-n+1} / 8,1-32^{-n+1} / 4\right] \\
& I_{n}^{3}=\left[1-32^{-n+1} / 4,1-2^{-n}\right]
\end{aligned}
$$

and

$$
\phi\left(1-72^{-n+1} / 8\right)=2^{-n / 2}, \phi\left(1-32^{-n+1} / 4\right)=2^{-n+1}
$$

(See Figure 1). Now set $a_{n}=2^{n} / n$ and define $f_{1}, f_{2}:[0, \bar{u}] \rightarrow \mathbf{R}$ by

$$
\begin{aligned}
& f_{1}(u)=a_{n}, \quad f_{2}(u)=0 \text { if } u \in I_{n}^{1} \\
& f_{1}(u)=a_{n}, \quad f_{2}(u)=-a_{n} \text { if } u \in I_{n}^{2} \\
& f_{1}(u)=0, \quad f_{2}(u)=0 \text { if } u \in I_{n}^{3}
\end{aligned}
$$

Observe that $\left(f_{1}, f_{2}\right) \in L_{1} \times L_{2}$, since $f_{i}$ is bounded on $\left[0, \tau_{\varepsilon}\right], \varepsilon>0, i=1,2$, and

$$
J_{1}\left(f_{1}, f_{2}\right)=\sum_{n \in \mathbb{N}} a_{n} I_{\left(I_{n}^{1} \cup I_{n}^{2}\right) \times\left[0,2^{-a+1}\right]}
$$

so

$$
\int_{\mathbf{R}_{+}^{2}}\left(J_{1}\left(f_{1}, f_{2}\right)(t)\right)^{2} d t=\sum_{n \in \mathbf{N}} \frac{2^{2 n}}{n^{2}} 2^{-n-1} 2^{-n+1}=\sum_{n \in \mathbb{N}} \frac{1}{n^{2}}<+\infty .
$$

On the other hand,

$$
\begin{aligned}
\int_{D_{1}}\left(f_{1}\left(t_{1}\right)\right)^{2} d t_{1} d t_{2} & =\sum_{n \in \mathbb{N}} a_{n}^{2}\left(2^{-2 n}+\frac{1}{2} 2^{-n-1} 2^{-n / 2}\right) \\
& =\sum_{n \in \mathbf{N}}\left(\frac{1}{n^{2}}+\frac{2^{n / 2-2}}{n^{2}}\right) \\
& =+\infty
\end{aligned}
$$

Similarly,

$$
\int_{D_{1}}\left(f_{2}(p(t))\right)^{2} d t_{1} d t_{2}=+\infty .
$$

5.4. Lemma. Set $\underset{\underline{L}}{\mathrm{~L}}=\left\{\left(\mathrm{f}_{1}, \mathrm{f}_{2}\right) \in \mathrm{L}_{1} \times \mathrm{L}_{2}: \mathrm{J}\left(\mathrm{f}_{1}, \mathrm{f}_{2}\right) \in \mathrm{L}^{2}(\mathrm{~T}, \mathrm{dt})\right\}$. For $\left(\mathrm{f}_{1}, \mathrm{f}_{2}\right) \in \underset{\underline{L}}{\mathrm{~L}}$, set

$$
I\left(f_{1}, f_{2}\right)=\int_{T} J\left(f_{1}, f_{2}\right)(t) d W_{t}
$$

(a) If $f_{1} \in L^{2}([0, \bar{u}], \phi(u) d u)$ and $f_{2} \in L^{2}\left([0, \bar{u}], d \mu_{2}\right)$ are Borel, then $\left(f_{1}, f_{2}\right) \in \underset{=}{L}$ and

$$
I\left(f_{1}, f_{2}\right)=\int_{0}^{\pi} f_{1}(u) d W_{u}^{1}+\int_{[0, \pi]} f_{2}(u) d \hat{W}_{u}
$$

(b) For all $\left(f_{1}, f_{2}\right) \in \underline{\underline{L}}, I\left(f_{1}, f_{2}\right) \in G(\Gamma)$.

Proof. Under the hypothesis of (a), we have

$$
\int_{0}^{1} f_{1}(u) d W_{u}^{1}=\int_{D^{1}} f_{1}\left(t_{1}\right) d W_{t_{1}, t_{2}}
$$

and

$$
\begin{aligned}
\int_{[0, \bar{u}]} f_{2}(u) d \hat{W}_{u} & =\int_{D_{1} \cup D_{2}} f_{2}(p(t)) d W_{t} \\
& =\int_{D_{1}} f_{2}(p(t)) d W_{t}+\int_{D_{2}} f_{2}(p(t)) d W_{t}
\end{aligned}
$$

so by definition of $J\left(f_{1}, f_{2}\right)$, the conclusion of (a) holds.
To see (b), observe that by Lemma $5.1(a), J_{i}\left(f_{1}, f_{2}\right) \in L^{2}(T, d t), i=1,2$. Since

$$
\int_{T} J_{2}\left(f_{1}, f_{2}\right)(t) d W_{t}=\int_{[0, \pi]} f_{2}(u) I_{p\left(D_{2}\right)}(u) d \hat{W}_{u} \in G(\Gamma)
$$

by Proposition 3.4, we only need to show that

$$
I_{1}\left(f_{1}, f_{2}\right)=\int_{\mathbf{R}_{+}^{2}} J_{1}\left(f_{1}, f_{2}\right)(t) d W_{t} \in G(\Gamma)
$$

Set $f_{i}^{\varepsilon}=f_{i} I_{\left[0, \tau_{e}\right]}, i=1,2, \varepsilon>0$. By Lemma 5.2 (c),

$$
Y_{1}^{\varepsilon}=\int_{0}^{\bar{u}} f_{1}^{\varepsilon}(u) d W_{u}^{1} \text { and } Y_{2}^{\varepsilon}=\int_{[0, \bar{u}]} f_{2}^{\varepsilon}(u) d \hat{W}_{u}
$$

are well-defined. These two variables belong to $G(\Gamma)$ by Theorem 3.8. Now

$$
\left\|J_{1}\left(f_{1}, f_{2}\right)-J_{1}\left(f_{1}^{\varepsilon}, f_{2}^{\varepsilon}\right)\right\| \leq\left\|J_{1}\left(f_{1}, f_{2}\right) I_{\left(D_{1}^{\ell}\right)}\right\|+\left\|\left(f_{2} \circ p\right) I_{\left[0, \tau_{e}\right] \times[0, \varepsilon]}\right\|
$$

The first term on the right-hand side tends to zero as $\varepsilon \rightarrow 0$, and

$$
\begin{aligned}
\left\|\left(f_{2} \circ p\right) I_{\left[0, \tau_{\varepsilon}\right] \times[0, \varepsilon]}\right\|^{2} & =\tau_{\varepsilon} \int_{0}^{\varepsilon}\left(f_{2} \circ p\left(0, f_{2}\right)\right)^{2} d t_{2} \\
& \leq \frac{\bar{u}}{s_{1}^{0}} \int_{\left[0, s_{1}^{0}\right] \times[0, \varepsilon]}\left(f_{2} \circ p(t)\right)^{2} d t \\
& \leq \frac{\bar{u}}{s_{0}^{1}} \int_{\left[0, s_{1}^{0}\right] \times[0, \varepsilon]} g^{2}(t) d t
\end{aligned}
$$

(the last inequality uses the same type of argument as in the proof of (5.6) and (5.7)). thus

$$
\begin{aligned}
I_{1}\left(f_{1}, f_{2}\right) & =\lim _{\varepsilon \rightarrow 0} \int_{T} J_{1}\left(f_{1}^{\varepsilon}, f_{2}^{\varepsilon}\right)(t) d W_{t}=\lim _{\varepsilon \rightarrow 0}\left(Y_{1}^{\varepsilon}+Y_{2}^{\varepsilon}\right) \\
& \in G(\Gamma) .
\end{aligned}
$$

The following theorem gives an explicit representation for $G(\Gamma)$.
5.5 Theorem. (a) $G(\Gamma)=\left\{I\left(f_{1}, f_{2}\right):\left(f_{1}, f_{2}\right) \in \underline{\underline{L}}\right\}$
(b) If $\left(f_{1}, f_{2}\right),\left(\tilde{f}_{1}, \tilde{f}_{2}\right) \in \underset{\underline{L}}{L}$, then $I\left(f_{1}, f_{2}\right)=I\left(\tilde{f}_{1}, \tilde{f}_{2}\right)$ if and only if there is $k \in \mathbf{R}$ such that

$$
\begin{gathered}
\mathrm{f}_{1}=\tilde{f}_{1}+\mathbf{k} \quad \mu_{1}-\text { a.s. } \\
\mathrm{f}_{2} \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{1}\right)}=\left(\tilde{f}_{2}-\mathrm{k}\right) \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{1}\right)} \quad \mu_{2}-\text { a.s. } \\
\mathrm{f}_{2} \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{2}\right)}=\tilde{\mathrm{f}}_{2} \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{2}\right)} \quad \mu_{2}-\text { a.s. }
\end{gathered}
$$

Proof. To prove (a), it is sufficient by Proposition 5.4 (b) to prove that $G(\Gamma) \subset \tilde{H}$, where $\tilde{H}=\left\{I\left(f_{1}, f_{2}\right):\left(f_{1}, f_{2}\right) \in \underline{\underline{L}}\right\}$. Since $\tilde{H}$ is a linear subspace containing the generators of $G(\Gamma)$, this inclusion will hold provided $\tilde{H}$ is closed in $L^{2}(\Omega, F, P)$. So suppose $\left(Y_{n}, n \in \mathbb{N}\right)$ is a sequence in $\tilde{H}$ converging in $L^{2}(\Omega, F, P)$ to $Y$, and $Y_{n}=I\left(f_{1}^{n}, f_{2}^{n}\right)$, where $\left(f_{1}^{n}, f_{2}^{n}\right) \in \underset{\equiv}{L}$, $f_{1}^{n}$ satisfies (6.3), for all $n \in \mathbb{N}$. We must show that $Y=I\left(f_{1}, f_{2}\right)$ for some $\left(f_{1}, f_{2}\right) \in \underline{=}$. Now convergence of $Y_{n}$ implies convergence in $L^{2}(T, d t)$ of $\left(J\left(f_{1}^{n}, f_{2}^{n}\right), n \in \mathbf{N}\right)$, to $g \in L^{2}(T, d t)$, say. By Lemma 5.1 (b), this implies $g=g^{1}+g^{2}$, where $g^{i}$ is the limit in $L^{2}(T, d t)$ of $\left(J_{i}\left(f_{1}^{n}, f_{2}^{n}\right), n \in \mathbb{N}\right)$, and $g^{2}(t)=h_{2}(p(t)) I_{D_{2}}(t)$, for some Borel $\mathrm{h}_{2}:[0, \overline{\mathrm{u}}] \rightarrow \mathbf{R}$.

By Lemma 5.2 (d), $g^{1}=J_{1}\left(\tilde{f}_{1}, \tilde{f}_{2}\right)$ for some couple $\left(\tilde{f}_{1}, \tilde{f}_{2}\right)$. We now set

$$
\mathrm{f}_{1}=\tilde{\mathrm{f}}_{1}, \mathrm{f}_{2}=\tilde{\mathrm{f}}_{2} \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{1}\right)}+\mathrm{h}_{2} \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{2}\right)}
$$

Clearly, $\mathrm{g}=\mathrm{J}\left(\mathrm{f}_{1}, \mathrm{f}_{2}\right)$.
(b) Suppose $I\left(f_{1}, f_{2}\right)=I\left(\tilde{f}_{1}, \tilde{f}_{2}\right)$. Choose $k, k^{\prime} \in \mathbf{R}$ so that $f_{1}^{k}$ and $\tilde{f}_{1}^{k}$ both satisfy (5.3). Then $I\left(f_{1}^{k}-f_{1}^{k^{\prime}}, f_{2}^{k}-f_{2}^{k^{\prime}}\right)=0$. So we only need to show that if $\left(f_{1}, f_{2}\right) \in \underline{L}$ satisfies (5.3) and $I\left(f_{1}, f_{2}\right)=0$, then $f_{1}=0 \mu_{1}$-a.s., $f_{2}=0 \mu_{2}$-a.s.

To begin with, equality (5.1) implies that

$$
\mathrm{J}_{1}\left(\mathrm{f}_{1}, \mathrm{f}_{2}\right)(\mathrm{t})=0 \mathrm{dt}-\mathrm{a} . \mathrm{s} . \text { and } \mathrm{f}_{2}(\mathrm{p}(\mathrm{t})) \mathrm{I}_{\mathrm{D}_{2}}(\mathrm{t})=0 \mathrm{dt}-\mathrm{a} . \mathrm{s} .
$$

This last is equivalent to $f_{2} \mathrm{I}_{p\left(D_{2}\right)}=0 \mu_{2}$-a.s. On the other hand, Lemma 5.2(c) implies $f_{1}=0 d \mu_{1}-$ a.s. and $f_{2} I_{p\left(D_{1}\right)}=0 d \mu_{2}$-a.s. Since

$$
\mu_{2}\left([0, \bar{u}] \backslash\left(p\left(D_{1}\right) \cup p\left(D_{2}\right)\right)=0\right.
$$

the conclusion follows.

We are now going to give properties of the elements of $G(\Gamma)$ which also belong to $H(\Gamma)$. We will do this only under a (weak) regularity assumption on $\phi$. These properties will lead to necessary and sufficient conditions for equality of the germ and sharp fields of $\Gamma$.

Let us introduce some notation. Set $\psi_{0}(u)=u$, and for $k \geq 1$, set

$$
\psi_{\mathbf{k}}(1:)=\left\{\begin{array}{lc}
\inf \left\{\mathrm{v}>\psi_{\mathrm{k}-1}(\mathrm{u}): \phi(\mathrm{v})=\phi(\mathrm{u})\right\} \text { if }\{ \} \neq \phi \\
+\infty & \text { otherwise }
\end{array}\right.
$$

and $\tau(u)=\sup \left\{k \geq 0: \psi_{k}(u)<+\infty\right\}$. We have the following elementary results.

### 5.6. Lemma.

(a) $\psi_{k}(u)<\psi_{k+1}(u)<+\infty \Rightarrow \psi_{k+1}(u) \in p\left(D_{1}\right) \cup p\left(D_{2}\right)$.
(b) $\psi_{\mathrm{k}+1}(\mathrm{u})=\psi_{\mathrm{k}} \circ \psi_{1}(\mathrm{u})=\psi_{1} \circ \psi_{\mathrm{k}}(\mathrm{u})$.
(c) $\tau(\mathrm{u})<+\infty \Rightarrow \tau\left(\psi_{\mathrm{k}+1}(\mathrm{u})\right)=\tau\left(\psi_{\mathrm{k}}(\mathrm{u})\right)-1,0 \leq \mathrm{k}<\tau(\mathrm{u})$.
(d) $\Psi_{\mathrm{k}}$ is Borel, $\mathrm{k} \geq 0$.
(e) $\tau$ is Borel.

Proof. (a) Observe that when $\psi_{\mathbf{k}}(u)<\psi_{\mathrm{k}+1}<+\infty$, we have either

$$
\psi_{\mathbf{k}}(\mathrm{u})<\mathrm{v}<\psi_{\mathrm{k}+1}(\mathrm{u}) \Rightarrow \phi(\mathrm{v})<\phi(\mathrm{u})
$$

or

$$
\psi_{\mathrm{k}}(\mathrm{u})<\mathrm{v}<\psi_{\mathrm{k}+1}(\mathrm{u}) \Rightarrow \phi(\mathrm{u})>\phi(\mathrm{u})
$$

In the first case, $\psi_{k+1}(u) \in p\left(D_{2}\right)$, and in the second $\psi_{k+1}(u) \in p\left(D_{1}\right)$.
(b) and (c) follow clearly from the definitions.
(d) By (b), it suffices to show that $\psi_{1}$ is Borel. Fix $u_{0} \in[0, \bar{u}]$. For $u \leq u_{0}$, set

$$
\mathrm{k}^{1}(\mathrm{u})=\sup \left\{\mathrm{v} \leq \mathrm{u}_{0}: l\left(\mathrm{v}, \mathrm{u}_{0}\right)=l\left(\mathrm{u}, \mathrm{u}_{0}\right)\right\}
$$

$$
k^{2}(u)=\sup \left\{v \leq u_{0}: L\left(v, u_{0}\right)=L\left(u, u_{0}\right)\right\}
$$

Then $k^{1}$ and $k^{2}$ are right-continuous, hence Borel, and

$$
\left\{u \in[0, \bar{u}]: \psi_{1}(u) \geq u_{0}\right\}=\left\{u \leq u_{0}: k^{1}(u)=u\right\} \cup\left\{u \leq u_{0}: k^{2}(u)=u\right\}
$$

This implies that $\psi_{1}$ is Borel.
Property (e) is a direct consequence of (d).

Throughout the remainder of this section, we shall be working under the following assumption on $\phi$.
5.7. Assumption. $\tau<\infty \mu_{2}$-a.s.

This assumption is implied by the following (weak) regularity assumption on $\phi$.
5.8. Proposition. Suppose that Banach's condition (T1) holds, that is, for $\mu_{1}$-almost all $\mathbf{x} \in \mathbb{R}_{+}$,

$$
E_{x}=\{u \in[0, \bar{u}]: \phi(u)=x\}
$$

is finite (see [S; Chap. IX. §6]). Then Assumption 5.7 holds.

Proof. The proof relies on the following fact: let ( $\mathrm{O}^{\mathbf{k}}, \mathrm{k} \in \mathbf{N}$ ) be a non-increasing sequence of subsets of $\mathbf{R}_{+}$, and set

$$
\mathbf{O}=\bigcap_{\mathbf{k} \in \mathbf{N}} \mathbf{O}^{\mathbf{k}}
$$

Then

$$
p\left(\left(D_{1} \cup D_{2}\right) \cap\left(\mathbb{R}_{+} \times \mathbf{O}\right)\right)=\bigcap_{k \in \mathbf{N}} p\left(\left(D_{1} \cup D_{2}\right) \cap\left(\mathbf{R}_{+} \times 0^{k}\right)\right)
$$

Indeed, " $c$ " is obvious. To see " $\supset$ ', suppose $u \in[0, \bar{u}]$ satisfies

$$
V k \in \mathbb{N}, \exists t^{k} \in\left(D_{1} \cup D_{2}\right) \cap\left(\mathbf{R}_{+} \times \mathbf{O}^{k}\right): p\left(t^{k}\right)=u
$$

By definition of $p$, there is $t_{2} \in \mathbf{R}_{+}$such that $t_{2}^{k}=t_{2}$, for all $k \in \mathbb{N}$. Thus

$$
\left(\mathrm{t}_{1}^{1}, \mathrm{t}_{2}\right) \in\left(\mathrm{D}_{1} \cup \mathrm{D}_{2}\right) \cap\left(\mathbb{R}_{+} \times \mathbf{O}\right) \text {, and } \mathrm{p}\left(\mathrm{t}_{1}^{1}, \mathrm{t}_{2}\right)=\mathrm{u}
$$

yielding the desired conclusion.
Now to prove the lemma, let $N \subset \mathbb{R}_{+}$be a $\mu_{1}$-null set such that $E_{x}$ is finite when $x \notin N$, and let $\left(O^{k}, k \in \mathbb{N}\right)$ be a non-increasing sequence of open sets containing $N$ such that $\mu_{1}(\mathbf{O} \backslash \mathrm{~N})=0$, where

$$
\mathbf{O}=\bigcap_{\mathbf{k} \in \mathbf{N}} \mathbf{0}^{\mathbf{k}}
$$

By the fact proved above and Lemma 3.2 (b),

$$
R=p\left(\left(D_{1} \cup D_{2}\right) \cap\left(\mathbb{R}_{+} \times \mathbf{O}\right)\right)
$$

is a Borel set, and clearly,

$$
\mathrm{p}^{-1}(\mathbf{R})=\left(\mathrm{D}_{1} \cup \mathrm{D}_{2}\right) \cap\left(\mathbf{R}_{+} \times \mathbf{O}\right) .
$$

Observe that if $u \in p\left(D_{1} \cup D_{2}\right) \backslash R$, then $\tau(u)$ is finite. Since $\mu_{2}\left(\left(p\left(D_{1} \cup D_{2}\right)\right)^{c}\right)=0$ and

$$
\mu_{2}(\mathbf{R})=\int_{\mathbf{R}_{+}^{2}} \mathrm{I}_{\left(\mathrm{D}_{1} \cup \mathrm{D}_{2}\right) \cap\left(\mathbf{R}_{+} \times \mathbf{0}\right)}(\mathrm{t}) \mathrm{dt}=0,
$$

the proof is complete.

Proposition 5.8 gives a large class of functions for which Assumption 5.7 holds. Indeed, necessary and sufficient conditions for Banach's condition (T1) to hold are given in [S; Chap. IX. Th. (6.2)]. In particular, (T1) holds if $\phi$ has bounded variation [S; Chap. IX. Th. (6.3)]. Condition (T1) is also satisfied by functions which are smooth except at finitely many points $u_{1}, \ldots, u_{k}$, in neighborhoods of which they resemble $c+\left(u-u_{i}\right) \sin \left(1 /\left(u-u_{i}\right)\right)$ or some other oscillating function. Finally, observe that $\tau(u)=+\infty$ if for some $\varepsilon>0, \phi$ is constant on $[u, u+\varepsilon]$. However, in this case, $\mu_{2}([u, u+\varepsilon])=0$, so the presence of such horizontal segments on $\Gamma$ does not affect Assumption 5.7.

An element $u_{0}$ of $[0, \bar{u}]$ is a strict local maximum (respectively minimum) of $\phi$ provided there is $\delta>0$ such that $\left|u-u_{0}\right|<\delta$ implies $\phi(u)<\phi\left(u_{0}\right)\left(\right.$ resp. $\phi(u)>\phi\left(u_{0}\right)$ ). A strict local extremum is a point which is either a strict local maximum or minimum. A point of increase of $\phi$ is an element $u_{0} \in[0, \bar{u}]$ such that for some $\varepsilon>0$,

$$
0<\delta<\varepsilon \Rightarrow \mathrm{L}\left(\mathrm{u}_{0}-\varepsilon, u_{0}-\delta\right)<\phi\left(\mathrm{u}_{0}\right)<l\left(\mathrm{u}_{0}+\delta, \mathrm{u}_{0}+\varepsilon\right) .
$$

A point of decrease is defined analogously.
5.9. Lemma. The following statements are implied by Assumption 5.7.
(a) Almost every $u \in[0, \bar{u}]$ (with respect to $\mu_{2}$ ) is a point of increase or decrease.
(b) For $\mu_{2}$-almost every $\mathrm{u} \in[0, \overline{\mathrm{u}}], \psi_{\mathbf{k}}(\mathrm{u})$ is a point of increase or decrease, for all $0 \leq \mathrm{k} \leq \tau(\mathrm{u})$.

Proof. (a) Under Assumption 5.7, we have

$$
\mu_{2}\left(\left(p\left(D_{1}\right) \cup p\left(D_{2}\right)\right) \cap\{\tau<+\infty\}\right)=\mu_{2}([0, \bar{u}])
$$

Fix $u \in\left(p\left(D_{1}\right) \cup p\left(D_{2}\right)\right) \cap\{\tau<+\infty\}$. Assume to begin with that $u \in p\left(D_{1}\right)$. Then there is $\varepsilon_{1}>0$ such that

$$
\begin{equation*}
0<\delta<\varepsilon_{1} \Rightarrow l\left(u-\varepsilon_{1}, u-\delta\right)>\phi(u) . \tag{5.12}
\end{equation*}
$$

Now since $\tau(u)<+\infty$, either there is $\varepsilon_{2}>0$ such that

$$
\begin{equation*}
0<\delta<\varepsilon_{2} \Rightarrow l\left(u+\delta, u+\varepsilon_{2}\right)>\phi(u) \tag{5.13}
\end{equation*}
$$

or

$$
\begin{equation*}
0<\delta<\varepsilon_{2} \Rightarrow L\left(u+\delta, u+\varepsilon_{2}\right)<\phi(u) . \tag{5.14}
\end{equation*}
$$

If (5.12) and (5.13) happen, $u$ is a strict local minimum. Since a continuous function has at most countably many strict local minima (see e.g. [S; Chap IX. Th. (1.1)]) and $\mu_{2}$ is diffuse, (5.14) holds for $\mu_{2}$-almost all $u$ in $p\left(D_{1}\right)$, i.e. $u$ is a point of decrease $\mu_{2}$-a.s.

A similar reasoning shows that if $u \in p\left(D_{2}\right) \cap\{\tau<+\infty\}$, then $u$ is $\mu_{2}$-a.s. a point of increase.
(b) We continue the reasoning begun in part (a). Set $Q=\left(p\left(D_{1}\right) \cup p\left(D_{2}\right)\right) \cap\{u: u$ is a strict local extremum $\}$. Then $Q$ is a countable set, and so $\phi(Q)$ is too. In particular, $[0, \bar{u}] \times \phi(Q)$ has two-dimensional Lebesguemeasure zero. Now

$$
\begin{gathered}
\left\{u \in\left(p\left(D_{1}\right) \cup p\left(D_{2}\right)\right) \cap\{\tau<+\infty\}: \psi_{k}(u)\right. \text { is not a point of increase or } \\
\text { decrease, for some } k \leq \tau(u)\}
\end{gathered}
$$

is contained in $p([0, \bar{u}] \times \phi(Q))$. Since

$$
\mu_{2}\left\{p(t): t_{2} \in \phi(Q)\right\} \leq \int_{[0, \bar{u}] \times \phi(Q)} d t=0,
$$

the lemma is proved.
5.10. Lemma. (a) Suppose $N \subset p\left(D_{1}\right) \cup p\left(D_{2}\right)$. Then

$$
\mu_{2}(\mathrm{~N})=0 \Longleftrightarrow \phi(\mathrm{~N}) \text { is a } \mu_{1}-\text { null set } .
$$

(b) Let $N \subset p\left(D_{1}\right) \cup p\left(D_{2}\right)$ be a $\mu_{2}$-null set. Then

$$
\mu_{2}\left\{u \in[0, \bar{u}]: \text { there is } k \in \mathbb{N} \text { s.t. } \psi_{k}(u) \in N\right\}=0
$$

Proof. (a) By definition,

$$
\mu_{2}(N)=\int_{D_{1} \cup D_{2}} L_{\mathrm{P}^{-1}(N)}(t) d t=\int_{0}^{L(0, \widetilde{u})} \mathrm{dt}_{2} \int_{0}^{\mathrm{k}\left(\mathrm{t}_{2}\right)} \mathrm{dt}_{1} \mathrm{~L}_{\mathrm{p}^{-1}(\mathbb{N})}\left(\mathrm{t}_{1}, \mathrm{t}_{2}\right),
$$

where $k\left(t_{2}\right)=\inf \left\{u: L(u, \bar{u})=t_{2}\right\}$. Now since $N \subset p\left(D_{1}\right) \cup p\left(D_{2}\right)$, the intersection of $p^{-1}(N)$ with any horizontal line $t_{2}=x$ is either the empty set if $x \notin \phi(N)$, or a countable union of horizontal segments if $x \in \phi(N)$. In particular,

$$
\mu_{2}(\mathrm{~N})=\int_{0}^{\mathrm{L}(0, \overline{\mathrm{u}})} \mathrm{dt}_{2} l\left(\mathrm{t}_{2}\right),
$$

where $l\left(t_{2}\right)>0 \Longleftrightarrow t_{2} \in \phi(N)$. This clearly implies (a).
(b) Observe that $\left\{u\right.$ : there is $k \in \mathbb{N}$ s.t. $\left.\psi_{\mathbf{k}}(u) \in N\right\} \subset \phi(N)$, so the conclusion follows from (a).

It will be convenient to number elements of a given level set from right to left instead of from left to right. On $\{\tau<+\infty\}$, set

$$
\tilde{\psi}_{i}(u)=\psi_{\tau(u)-i}(u), \quad 0 \leq i \leq \tau(u) .
$$

Provided $\tilde{\psi}_{k}(u)$ is a point of increase or decrease, for $0 \leq k \leq \tau(u)$, we have $\tilde{\psi}_{2 i}(u) \in p\left(D_{1}\right)$ if $2 i \leq \tau(u)$ and $\tilde{\psi}_{2 i+1} \in p\left(D_{2}\right)$ if $2 i+1 \leq \tau(u)$.

If $f:[0, \bar{u}] \rightarrow \mathbf{R}$ is Borel, we set $f(+\infty)=0$, and define two Borel functions $\alpha_{1}(f)$, $\alpha_{2}(f):[0, \bar{u}] \rightarrow \mathbf{R}$ by

$$
\begin{aligned}
& \alpha_{1}(f)(u)=f(u), \\
& \alpha_{2}(f)(u)=\left[\sum_{0 \leq 2 i+1 \leq \tau(u)} f\left(\tilde{\Psi}_{2 i+1}(u)\right)-\sum_{0 \leq 2 i \leq \tau(u)} f\left(\tilde{\Psi}_{2 i}(u)\right)\right] I_{\{\tau<+\infty\}}(u),
\end{aligned}
$$

and set $K(f)=J\left(\alpha_{1}(f), \alpha_{2}(f)\right), L(f)=I\left(\alpha_{1}(f), \alpha_{2}(f)\right)$ if $K(f) \in L^{2}(T, d t)$.
Fix $\mathrm{a}, \mathrm{b} \in \mathbf{R}$, and suppose $\mathrm{f}_{1}, \mathrm{f}_{2}:[0, \bar{u}] \rightarrow \mathbf{R}$ are Borel.
5.11. Lemma. (a) We have $K\left(a f_{1}+b f_{2}\right)=a K\left(f_{1}\right)+b K\left(f_{2}\right)$ and $K\left(f_{1}+a\right)=K\left(f_{1}\right)$.
(b) Assume in addition that $\left(\alpha_{1}\left(f_{i}\right), \alpha_{2}\left(f_{i}\right)\right) \in L_{1} \times L_{2}, i=1,2$. Then $L\left(f_{1}\right)=L\left(f_{2}\right)$ if and only if there is $k \in R$ such that $f_{1}=f_{2}+k \mu_{1}-$ a.s. and $\mu_{2}$-a.s.

Proof. The first statement in (a) holds because $\alpha_{1}$ and $\alpha_{2}$ depend linearly on $f$ and the definition of J implies
$J\left(a \alpha_{1}\left(f_{1}\right)+b \alpha_{1}\left(f_{2}\right), a \alpha_{2}\left(f_{1}\right)+b \alpha_{2}\left(f_{2}\right)\right)=a J\left(\alpha_{1}\left(f_{1}\right), \alpha_{2}\left(f_{1}\right)\right)+b J\left(\alpha_{1}\left(f_{2}\right), \alpha_{2}\left(f_{2}\right)\right)$.
To prove the second statement in (a), note that

$$
\begin{aligned}
& \tau(u)=0 \Rightarrow \alpha_{2}\left(f_{1}+a\right)(u)=\alpha_{2}\left(f_{1}\right)(u)-a, \\
& \tau(u)=1 \Rightarrow \alpha_{2}\left(f_{1}+a\right)(u)=\alpha_{2}\left(f_{1}\right)(u),
\end{aligned}
$$

and by induction, we get for $u \in\{\tau<+\infty\}$ that

$$
\begin{aligned}
& u \in p\left(D_{1}\right) \Rightarrow \alpha_{2}\left(f_{1}+a\right)(u)=\alpha_{2}\left(f_{1}\right)(u)-a \\
& u \in p\left(D_{2}\right) \Rightarrow \alpha_{2}\left(f_{1}+a\right)(u)=\alpha_{2}\left(f_{1}\right)(u) .
\end{aligned}
$$

But since $\alpha_{1}\left(f_{1}+a\right)=\alpha_{1}\left(f_{1}\right)+a$, Theorem 5.5 (b) implies that $K\left(f_{1}+a\right)=K\left(f_{1}\right)$.
(b) Suppose $f_{1}=f_{2}+k \mu_{1}$ and $\mu_{2}$-a.s. Then $\alpha_{1}\left(f_{1}\right)=\alpha_{1}\left(f_{2}+k\right) \mu_{1}$-a.s. and $\alpha_{2}\left(f_{1}\right)=\alpha_{2}\left(f_{2}+k\right) \mu_{2}$-a.s., so by (a),

$$
L\left(f_{1}\right)=L\left(f_{2}+k\right)=L\left(f_{2}\right) .
$$

To show the converse, assume $L\left(f_{1}\right)=L\left(f_{2}\right)$. We then use Theorem 5.5 (b) to get $\mathbf{k} \in \mathbf{R}$ such that

$$
\begin{align*}
\alpha_{1}\left(f_{1}\right) & =\alpha_{1}\left(f_{2}\right)+k \quad \mu_{1} \text { a.s. } \\
\alpha_{2}\left(f_{1}\right) I_{p\left(D_{1}\right)} & =\left(\alpha_{2}\left(f_{2}\right)-k\right) L_{p\left(D_{1}\right)} \quad \mu_{2}-\text { a.s. }  \tag{5.15}\\
\alpha_{2}\left(f_{1}\right) I_{p\left(D_{2}\right)} & =\alpha_{2}\left(f_{2}\right) I_{p\left(D_{2}\right)} \quad \mu_{2}-\text { a.s. } \tag{5.16}
\end{align*}
$$

Let N be a $\mu_{2}$-null set outside of which (5.15) and (5.16) hold. By Lemma 5.10 (b), we may assume that

$$
\tau(u)<+\infty \Rightarrow \psi_{\mathbf{k}}(\mathrm{u}) \notin \mathrm{N} \cap\left(\mathrm{p}\left(\mathrm{D}_{1}\right) \cup \mathrm{p}\left(\mathrm{D}_{2}\right)\right), 0 \leq \mathrm{k} \leq \tau(\mathrm{u}) .
$$

But then, when $u \notin N$ and $\tau(u)<+\infty, \tilde{\psi}_{0}(u) \in p\left(D_{1}\right)$, so by (5.15),

$$
-\mathrm{f}_{1}\left(\tilde{\psi}_{0}(\mathrm{u})\right) \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{1}\right)}(\mathrm{u})=\left(\alpha_{2}\left(\mathrm{f}_{1}\right)\left(\tilde{\psi}_{0}(\mathrm{u})\right)-\mathrm{k}\right) \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{1}\right)}(\mathrm{u})=-\mathrm{f}_{2}\left(\tilde{\psi}_{0}(\mathrm{u})\right)-\mathrm{k} .
$$

We then use (5.16) and the fact that $\tilde{\psi}_{1}(u) \in p\left(D_{2}\right)$ to get $f_{1}\left(\tilde{\psi}_{1}(u)\right)=f_{2}\left(\tilde{\psi}_{1}(u)\right)+k$ (if $\tau(\mathrm{u}) \geq 1$ ). By induction, we get for $\mu_{2}$-almost all u

$$
\mathrm{f}_{1}\left(\tilde{\Psi}_{l}(\mathrm{u})\right)=\mathrm{f}_{2}\left(\tilde{\Psi}_{l}(\mathrm{u})\right)+\mathrm{k}, 0 \leq l \leq \tau(\mathrm{u}) .
$$

Setting $l=\tau(\mathrm{u})$ gives the desired result.

Set $\tilde{H}(\Gamma)=\{Y \in G(\Gamma)$ : there is $f$ Borel such that $Y=L(f)\}$.
The following lemma gives, under Assumption 5.7, a characterization of the elements of $Y$ of $G(\Gamma)$ which belong to $\tilde{H}(\Gamma)$. It is a generalization of [DR; Lemma 3.11].
5.12. Proposition Let $\left(f_{1}, f_{2}\right) \in \underset{\underline{L}}{L}$. Then $Y=I\left(f_{1}, f_{2}\right) \in \tilde{H}(\Gamma)$ if and only if there is a
$\mu_{i}$-null set $N_{i}, i=1,2$, such that if $u \in[0, \bar{u}] \backslash\left(N_{1} \cup N_{2}\right)$, then

$$
\begin{equation*}
f_{1}(u) I_{p\left(D_{1}\right)}(u)=\left(-f_{2}(u)+f_{2}\left(\psi_{1}(u)\right)\right) I_{p\left(D_{1}\right)}(u) \tag{5.17}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathrm{f}_{1}(\mathrm{u}) \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{2}\right)}(\mathrm{u})=\left(\mathrm{f}_{2}(\mathrm{u})-\mathrm{f}_{2}\left(\Psi_{1}(\mathrm{u})\right)\right) \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{2}\right)}(\mathrm{u}) \tag{5.18}
\end{equation*}
$$

Proof. If $Y=I\left(f_{1}, f_{2}\right)=L(f)$ for some Borel $f:[0, \bar{u}] \rightarrow \mathbb{R}$, then (5.17) and (5.18) follows from Theorem 5.5 (b) and the definitions of $\alpha_{1}(f)$ and $\alpha_{2}(f)$. Now suppose (5.17) and (5.18) hold. We define $f:[0, \bar{u}] \rightarrow \mathbf{R}$ successively on the sets $\{\tau=0\}$, $\{\tau=1\}, \ldots$ as follows. First, we define $f$ on the set $\{\tau=0\}$ by setting

$$
\mathrm{fI}_{\{\tau=0\}}=\left(\mathrm{f}_{1} \mathrm{I}_{\mathrm{N}_{\mathrm{i}}}-\mathrm{f}_{2} \mathrm{I}_{\mathrm{N}_{1}}\right) \mathrm{I}_{\{\tau=0\}}
$$

and then, assuming by induction that $f$ has been defined on $\{\tau=k-1\}$, we set

$$
\begin{equation*}
\mathrm{fI}_{\{\tau=\mathrm{k}\}}=\left(\mathrm{f}_{1} \mathrm{I}_{\mathrm{N}_{\mathrm{i}}^{c}}+\left(\mathrm{f}_{2}-\mathrm{f}_{2} \circ \psi_{1}\right) \mathrm{I}_{\mathrm{N}_{1}}\right) \mathrm{I}_{\{\tau=\mathrm{k}\}} \tag{5.19}
\end{equation*}
$$

if $k$ is odd, and

$$
\begin{equation*}
\mathrm{fI}_{\{\tau=\mathrm{k}\}}=\left(\mathrm{f}_{1} \mathrm{I}_{\mathrm{N}_{\mathrm{i}}^{c}}+\left(-\mathrm{f}_{2}+\mathrm{f}_{2} \circ \Psi_{1}\right) \mathrm{I}_{\mathrm{N}_{1}}\right) \mathrm{I}_{\{\tau=\mathrm{k}\}} \tag{5.20}
\end{equation*}
$$

if $k$ is even. This defines $f$ on $\{\tau<+\infty\}$, and we set

$$
\mathrm{fI}_{\{\tau=+\infty\}}=\mathrm{f}_{1} \mathrm{I}_{\{\tau=+\infty\}}
$$

Clearly, $\mathrm{f}_{1}(\mathrm{u})=\alpha_{1}(\mathrm{f})(\mathrm{u}), \mathrm{u} \notin \mathrm{N}_{1}$.
By Lemma 5.10 (b), let $N_{2}^{\prime}$ be a $\mu_{2}$-null set such that $u \notin N_{2}^{\prime}$ implies $\psi_{k}(u) \notin N_{2} \cap\left(p\left(D_{1}\right) \cup p\left(D_{2}\right)\right), 0 \leq k \leq \tau(u)$. Clearly $N_{2}{ }^{\prime} \supset N_{2}$, and if $u \notin N_{2}^{\prime}$, we have by (5.17)

$$
\begin{aligned}
\alpha_{2}(f)(u) I_{\{\tau=0\}} & =-f(u) I_{\{\tau=0\}}(u)=-\left(f_{1}(u) I_{N_{1}^{c}}(u)-f_{2}(u) I_{N_{1}}(u)\right) I_{\{\tau=0\}} \\
& =f_{2}(u) I_{\{\tau=0\}}
\end{aligned}
$$

Similarly, equations (5.19) and (5.20) become respectively

$$
\begin{aligned}
& \mathrm{fI}_{(\tau=\mathrm{k}) \backslash \mathrm{N}_{2}^{\prime}}=\left(\mathrm{f}_{2}-\mathrm{f}_{2} \circ \psi_{1}\right) \mathrm{I}_{(\tau=\mathrm{k}\} \backslash \mathrm{N}^{\prime}{ }^{\prime}}, \mathrm{k} \text { odd }, \\
& f I_{(\tau=k) \backslash N_{2}^{\prime}}=\left(-f_{2}+f_{2} \circ \Psi_{1}\right) I_{(\tau=k) \backslash N_{2}^{\prime}}, k \text { even. }
\end{aligned}
$$

Proceeding by induction on k , one checks that

$$
\alpha_{2}(\mathrm{f})(\mathrm{u})=\mathrm{f}_{2}(\mathrm{u}), \mathrm{u} \in\{\tau<+\infty\} \backslash \mathrm{N}_{2}^{\prime} .
$$

Since $\mu_{2}\left(\{\tau<+\infty\} \backslash N_{2}{ }^{\prime}\right)=\mu_{2}([0, \bar{u}])$, we have shown that $\alpha_{i}(f)=f_{i} \mu_{i}$-a.s., $i=1,2$. Thus

$$
\mathrm{Y}=\mathrm{I}\left(\mathrm{f}_{1}, \mathrm{f}_{2}\right)=\mathrm{L}(\mathrm{f}),
$$

concluding the proof.
5.13. Lemma. (a) Fix $0 \leq u_{0} \leq \bar{u}$. If $f=I_{\left[0, u_{0}\right]}$, then $L(f)=W_{u_{0}, \phi\left(u_{0}\right)}$.
(b) $\tilde{\mathrm{H}}(\Gamma)$ is a closed linear subspace of $\mathrm{G}(\Gamma)$.

Proof. (a) To begin with, we have in this case $\alpha_{1}(f)=I_{\left[0, u_{0}\right]}$, and clearly $\alpha_{2}(f)(u)=0$ if $u>u_{0}$. In addition, we will check by induction that $\mu_{2}$-a.s., if $\phi(u)>\phi\left(u_{0}\right)$ then

$$
\begin{aligned}
& u \in p\left(D_{1}\right) \Rightarrow \alpha_{2}(f)(u)=-1, \\
& u \in p\left(D_{2}\right) \Rightarrow \alpha_{2}(f)(u)=0,
\end{aligned}
$$

whereas if $\phi(u)<\phi\left(u_{0}\right)$, then

$$
\begin{aligned}
& u \in p\left(D_{1}\right) \Rightarrow \alpha_{2}(f)(u)=0, \\
& u \in p\left(D_{2}\right) \Rightarrow \alpha_{2}(f)(u)=1 .
\end{aligned}
$$

Indeed, if $\tau(u)<+\infty$, let $u=v_{0}<v_{1}<\cdots<v_{k}<u_{0}$ be such that

$$
\left\{v_{0}, \ldots, v_{k}\right\}=\left\{v \in\left[u, u_{0}\right]: \phi(v)=\phi(u)\right\} .
$$

Now if $u \in p\left(D_{1}\right), u$ is a point of decrease of $\phi$, and so when $\phi(u)>\phi\left(u_{0}\right), k$ must be even. On the other hand, if $\phi(u)<\phi\left(u_{0}\right)$, then $k$ will be odd. Together with a similar argument for $p\left(D_{2}\right)$, all four implications above follow from the definition of $\alpha_{2}(f)$.

It is then easy to see that

$$
K(f)=J\left(\alpha_{1}(f), \alpha_{2}(f)\right)=I_{R_{R_{0}, 0}\left(\alpha_{0}\right)} d t-\text { a.s. },
$$

and thus $I(f)=W_{u_{0}, \phi\left(u_{0}\right)}$.
(b) Let ( $\mathrm{Y}^{\mathrm{n}}, \mathrm{n} \in \mathbb{N}$ ) be a sequence of elements of $\tilde{H}(\Gamma)$ converging to Y in $L^{2}(\Omega, \underset{=}{F}, P)$. Since $G(\Gamma)$ is closed, $Y \in G(\Gamma)$. By Theorem 5.5 , there is $\left(f_{1}^{n}, f_{2}^{n}\right) \in \underline{L}$ and $\left(f_{1}, f_{2}\right) \in \underline{\underline{L}}$ such that $Y^{n}=I\left(f_{1}^{n}, f_{2}^{n}\right), n \in \mathbb{N}$, and $Y=I\left(f_{1}, f_{2}\right)$. We may of course assume that $f_{1}^{n}$ and $f_{1}$ satisfy (5.3). But then Lemmas 5.1 (b) and $5.2(\mathrm{~d})$ imply that for each $\varepsilon>0$,

$$
\begin{aligned}
& f_{1} I_{\left[0, \tau_{]}\right]}=\lim _{n \rightarrow \infty} f_{1}^{n} I_{\left[0, \tau_{z}\right]} \text { in } L^{2}\left([0, \bar{u}], d \mu_{1}\right), \\
& f_{2} I_{\left[0, \tau_{\varepsilon}\right]}=\lim _{n \rightarrow \infty} f_{2}^{n} I_{\left[0, \tau_{\varepsilon}\right]} \text { in } L^{2}\left([0, \bar{u}], d \mu_{2}\right) .
\end{aligned}
$$

Using a diagonal subsequence argument, we get (Borel) sets $M_{1}$ and $M_{2}$ with
$\mu_{i}\left(M_{i}\right)=0, i=1,2$, and subsequences $\left(f_{1}^{n_{k}}, k \in \mathbb{N}\right)$ and $\left(f_{2}^{n_{k}}, k \in \mathbb{N}\right)$ such that

$$
\begin{equation*}
\mathrm{f}_{\mathrm{i}}(\mathrm{u})=\lim _{\mathrm{n} \rightarrow \infty} \mathrm{f}_{\mathrm{i}}^{\mathrm{n}_{\mathrm{k}}}(\mathrm{u}), \mathrm{u} \in \mathrm{M}_{\mathrm{i}}, \mathrm{i}=1,2 \tag{5.21}
\end{equation*}
$$

Since $Y^{n_{k}} \in \tilde{H}(\Gamma)$, Proposition 5.12 affirms the existence of $\mu_{i}$-null sets $N_{i}^{k}, i=1,2$, such that if $u \in[0, \bar{u}] \backslash\left(N_{1}^{k} \cup N_{2}^{k}\right)$,

$$
\begin{align*}
& f_{1}^{n_{1}}(u) I_{p\left(D_{1}\right)}(u)=\left(-f_{2}^{n_{k}}(u)+f_{2}^{n_{x}}\left(\Psi_{1}(u)\right)\right) I_{p\left(D_{1}\right)}(u), \\
& \mathrm{f}_{2}^{\mathrm{n}_{\mathrm{k}}}(\mathrm{u}) \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{2}\right)}(\mathrm{u})=\left(\mathrm{f}_{2}^{\mathrm{n}_{k}}(\mathrm{u})-\mathrm{f}_{2}^{\mathrm{n}_{\mathrm{x}}}\left(\Psi_{1}(u)\right) \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{2}\right)}(\mathrm{u})\right. \text {. } \tag{5.22}
\end{align*}
$$

Now set

$$
N_{1}^{\prime}=\left(\bigcup_{k \in \mathbf{N}} N_{1}^{k}\right) \cup M_{1}, N_{2}^{\prime}=\left(\bigcup_{k \in \mathbf{N}} N_{2}^{k}\right) \cup M_{2} .
$$

By Lemma 5.10 (b), there is a $\mu_{2}$-null set $\mathrm{N}_{2}{ }^{\prime \prime} \supset \mathrm{N}_{2}{ }^{\prime}$ such that $\mathrm{u} \notin \mathrm{N}_{2}{ }^{\prime \prime} \Rightarrow \psi_{1}(\mathrm{u}) \notin \mathrm{N}_{2}{ }^{\prime} \cap\left(\mathrm{p}\left(\mathrm{D}_{1}\right) \cup \mathrm{p}\left(\mathrm{D}_{2}\right)\right)$. Finally, we set

$$
N_{2}=N_{2}{ }^{\prime \prime} \cup\left(p\left(D_{1}\right) \cup p\left(D_{2}\right)\right)^{c} \cup\{\tau=+\infty\}
$$

which is a $\mu_{2}$-null set, such that

$$
u \notin N_{2} \Rightarrow\left(u \notin N_{2}^{k} \cup M_{2} \text { and } \psi_{1}(u) \notin N_{2}^{k} \cup M_{2}\right) .
$$

We can now pass to the limit in (5.22) using (5.21), to see that if $u \in[0, \bar{u}] \backslash\left(N_{1} \cup N_{2}\right)$, then

$$
\begin{aligned}
& \mathrm{f}_{1}(\mathrm{u}) \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{1}\right)}(\mathrm{u})=\left(-\mathrm{f}_{2}(\mathrm{u})+\mathrm{f}_{2}\left(\Psi_{1}(\mathrm{u})\right)\right) \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{1}\right)}(\mathrm{u}), \\
& \mathrm{f}_{2}(\mathrm{u}) \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{2}\right)}(\mathrm{u})=\left(\mathrm{f}_{2}(\mathrm{u})+\mathrm{f}_{2}\left(\Psi_{1}(\mathrm{u})\right)\right) \mathrm{I}_{\mathrm{p}\left(\mathrm{D}_{2}\right)}(\mathrm{u})
\end{aligned}
$$

By Proposition 5.12 this means that $Y \in \tilde{H}(\Gamma)$, concluding the proof.

The following theorem is a generalization of [DR; Theorem 3.12], which contains the case " $\phi$ monotone non-increasing".
5.14. Theorem. Suppose $\phi$ satisfies Assumption 5.7. Then the following conditions are equivalent:
(a) $\underset{=}{\mathrm{H}}(\Gamma)=\underline{\underline{G}}(\Gamma)$;
(b) $W\left(D_{1}\right)$ is $\underset{\underline{H}}{H}(\Gamma)$-measurable:
(c) $\mu_{1}$ and $\mu_{2}$ are mutually singular.

Proof. $(a) \Rightarrow(b)$. This follows from Proposition 3.1 and the fact that $\mathrm{W}\left(\mathrm{D}_{1}\right)=\mathrm{W}_{\mathbf{u}}^{1}$.
(b) $\Rightarrow(c)$. Note that $W\left(D_{1}\right)=I\left(f_{1}, f_{2}\right)$ where $f_{1} \equiv 1$ and $f_{2} \equiv 0$. Now if $W\left(D_{1}\right)$ belongs to $\underset{=}{H}(\Gamma)$, it will in fact belong to $H(\Gamma)$. In particular, by Lemma 5.13, W ( $D_{1}$ ) would belong to $\tilde{H}(\Gamma)$. But then Proposition 5.12 would yield $\mu_{i}$-null sets $\mathrm{N}_{\mathrm{i}}, \mathrm{i}=1,2$ such that

$$
u \in[0, \bar{u}] \backslash\left(N_{1} \cup N_{2}\right) \Rightarrow 1 I_{p\left(D_{1}\right) u p p_{p}\left(D_{2}\right)}=0
$$

This means that $p\left(D_{1}\right) \cup p\left(D_{2}\right) \subset N_{1} \cup N_{2}$. Since

$$
\mu_{2}\left([0, \bar{u}] \backslash\left(p\left(D_{1}\right) \cup p\left(D_{2}\right)\right)\right)=0
$$

we can assume that

$$
[0, \bar{u}] \backslash\left(p\left(D_{1}\right) \cup p\left(D_{2}\right)\right) \subset N_{2} .
$$

But then $[0, \bar{u}]=N_{1} \cup N_{2}$, with $\mu_{i}\left(N_{i}\right)=0, i=1,2$, so $\mu_{1}$ and $\mu_{2}$ are mutually singular.
$(c) \Rightarrow(a)$. By Remark 4.11, it suffices to show that

$$
\mathrm{u} \mapsto \mathrm{~L}\left(\mathrm{u}_{0}, \mathrm{u}\right) \text { and } \mathrm{u} \mapsto l\left(\mathrm{u}_{0}, \mathrm{u}\right)
$$

are singular functions, for all $u_{0} \in[0, \bar{u}]$. But this is a consequence of Proposition 6.1 (a) below.
5.15. Corollary. Assume $\phi$ has bounded variation. Then $\underset{=}{\mathrm{H}}(\Gamma)=\underset{\underline{G}}{\mathrm{G}}(\Gamma)$ if and only if $\phi$ is singular with respect to Lebesgue measure.

Proof. This is an immediate consequence of Theorem 5.14 and Proposition 6.7 (b) below.

## 6. Conditions under which $\mu_{2}$ is singular with respect to Lebesgue-measure.

In view of Theorem 5.14, it becomes of interest to determine for which functions $\phi$ the measures $\mu_{1}$ and $\mu_{2}$ are mutually singular. The following proposition gives a complete answer when $\phi$ has bounded variation, and, in the general case, relates the property to singularity of $l\left(u_{0}, \cdot\right)$ and $L\left(u_{0}, \cdot\right), u_{0} \in[0, \bar{u}]$.

### 6.1. Proposition.

(a) For an arbitrary continuous function $\phi$, the following two conditions are equivalent.
(6.1) There is a countable dense set $\mathrm{Q} \subset\left[0, \mathrm{u}_{0}\right]$ such that $l\left(\mathrm{u}_{0}, \cdot\right)$ and $\mathrm{L}\left(\mathrm{u}_{0}, \cdot\right)$ are singular (with respect to Lebesgue measure), $\mathrm{Vu}_{0} \in \mathrm{Q}$.
(6.2) $\mu_{2}$ is singular with respect to Lebesgue measure.
(b) If $\phi$ has bounded variation, then (6.2) holds if and only if $\phi$ is a singular function.

Proof. (6.1) $\Rightarrow$ (6.2). Observe that there is a sequence of rectangles $\left(R_{k}=\left[a^{k}, b^{k}\right] \times\right.$ $\left[c^{k}, d^{k}\right], k \in \mathbb{N}$ ), where each $R_{k}$ is contained either in $D_{1}$ or in $D_{2}$, such that

$$
\mathrm{E}_{\mathrm{k}} \cap \mathrm{E}_{l}=\phi \text { a.s., } \mathrm{k} \neq l \text {, and } \cup_{\mathbf{k}} \mathrm{E}_{\mathrm{k}}=\mathrm{D}_{1} \cup \mathrm{D}_{2},
$$

where $E_{k}=\left(D_{1} \cup D_{2}\right) \cap p^{-1}\left(p\left(R_{k}\right)\right)$. It is thus sufficient to show that for a fixed rectangle $\left.R={ }_{i} a, b\right] \times[c, d](a<b, c<d)$, the restriction of $\mu_{2}$ to the Borel set $p(R)$ is singular with respect to $\mu_{1}$. We only examine the case $R \subset D_{1}$, since the case $R \subset D_{2}$ is similar.

Let $u_{0} \in Q \cap[a, b]$, and set $f(u)=l\left(u_{0}, u\right), u \geq u_{0}$. By (6.1), there is a Borel set $\mathrm{N} \subset \mathrm{p}(\mathrm{R})$ such that $\mu_{1}(\mathrm{~N})=0$ and $\mathrm{p}(\mathrm{R}) \backslash \mathrm{N}$ is a df-null set. By the above considerations, the proof will be complete provided we show that $\mu_{2}(p(R) \backslash N)=0$.

For $\mathrm{c} \leq \mathrm{t}_{2} \leq \mathrm{d}$, set $l\left(\mathrm{t}_{2}\right)=\mathrm{p}\left(\mathrm{u}_{0}, \mathrm{t}_{2}\right)-\mathrm{q}\left(\mathrm{u}_{0}, \mathrm{t}_{2}\right)$, where

$$
q\left(u_{0}, t_{2}\right)=\left\{\begin{array}{l}
\sup \left\{u \leq u_{0}: \phi(u)=t_{2}\right\} \text { if }\{\quad\} \neq \phi, \\
0 \\
\text { otherwise } .
\end{array}\right.
$$

We then have (recall that $\hat{\mathrm{f}}^{-1}$ is defined prior to Lemma 4.1)

$$
\begin{aligned}
\mu_{2}(\mathrm{p}(\mathrm{R}) \backslash \mathrm{N}) & =\int_{\mathbf{R}^{+}} \mathrm{L}_{\mathrm{p}^{-1}}(\mathrm{p}(\mathrm{R}) \backslash \mathrm{N})(\mathrm{t}) \mathrm{dt} \\
& =\int_{\mathrm{c}}^{\mathrm{d}} \mathrm{dt}_{2} l\left(\mathrm{t}_{2}\right) \mathrm{I}_{\left(\mathrm{f}^{-1} d \mathrm{~N}\right)}\left(\mathrm{t}_{2}\right) \\
& \leq \int_{\mathrm{c}}^{\mathrm{d}} \mathrm{dt}_{2} \hat{\mathrm{f}}^{-1}\left(\mathrm{t}_{2}\right) \mathrm{I}_{\mathrm{N}^{c}}\left(\mathrm{f}^{-1}\left(\mathrm{t}_{2}\right)\right) \\
& =\int_{\hat{\mathrm{F}}^{-1}(\mathrm{~d})}^{\hat{\mathrm{C}}^{-1}(\mathrm{c})} \mathrm{u} \mathrm{I}_{\mathrm{N}^{c}}(\mathrm{u}) \mathrm{df}(\mathrm{u}) \\
& =0
\end{aligned}
$$

(the last equality uses the change of variables formula of [DM; Chap. VI. 2, (55.1)]). This completes the proof of $(6.1) \Rightarrow(6.2)$.
(6.2) $\Rightarrow$ (6.1). We shall only prove that $f(u)=l\left(u_{0}, u\right)$ is singular with respect to $\mu_{1}$, for all $u_{0} \in[0, \bar{u}]$, since the other case is similar.

Since $\phi$ is continuous at $u_{0}$, for any fixed $\varepsilon>0$, there exist $a, b$ and $d$ such that

$$
a<u_{0}<b, \phi\left(u_{0}\right)-\varepsilon<d<\phi\left(u_{0}\right)
$$

and $R=[a, b] \times[0, d] \subset D_{1}$. By (6.2), there is a Borel set $N$ with Lebesgue measure 1 such that $\mu_{2}(N)=0$. Since

$$
l\left(\mathrm{t}_{2}\right) \backslash \hat{\mathrm{f}}^{-1}\left(\mathrm{t}_{2}\right) \geq(\mathrm{b}-\mathrm{a}) \backslash \overline{\mathrm{u}}, 0 \leq \mathrm{t}_{2} \leq \mathrm{d},
$$

we get

$$
\begin{aligned}
& 0=\mu_{2}(\mathrm{p}(\mathrm{R}) \cap \mathrm{N}) \\
&=\int_{\mathrm{D}_{1}} \mathrm{~L}_{\mathrm{p}}^{-1}(\mathrm{p}(\mathrm{R}) \cap \mathrm{N}) \\
&=\int_{0}^{\mathrm{d}} l(\mathrm{t}) \mathrm{dt} \\
& \geq \frac{\mathrm{b}-\mathrm{a}}{\overline{\mathrm{u}}} \int_{0}^{\mathrm{d}} \mathrm{I}_{\mathrm{p}}^{-1}(\mathrm{p}(\mathrm{R}) \cap \mathrm{N})\left(\mathrm{u}_{0}, \mathrm{t}_{2}\right) \mathrm{ft}_{2}\left(\mathrm{t}_{2}\right) \mathrm{I}_{\mathrm{N}}\left(\hat{\mathrm{f}}^{-1}\left(\mathrm{t}_{2}\right)\right) \mathrm{dt}_{2} \\
&\left.=\frac{\mathrm{b}-\mathrm{a}}{\overline{\mathrm{u}}} \int_{\overline{\mathrm{u}}} \hat{\mathrm{f}}^{-1} \mathrm{~d}\right) \\
& \mathrm{u} \\
& \mathrm{~N}
\end{aligned}
$$

Thus $N \cap\left[f^{-1}(d), \bar{u}\right]$ is a df-null set. Since $\varepsilon$ was arbitrary, $N \cap\left[u_{0}, \bar{u}\right]$ is a df-null set. But this implies that f is singular with respect to $\mu_{1}$, concluding the proof of (6.2) $\Rightarrow$ (6.1).

We now turn to the proof of (b). To begin with, assume $\phi$ is singular. By (a), it is sufficient to show that $l\left(u_{0}, \cdot\right)$ and $L\left(u_{0}, \cdot\right)$ are singular, for all $u_{0} \in[0, \bar{u}]$. In Example 4.10 (a), this was done for $L\left(u_{0}, \cdot\right)$, and the other case is similar.

We now show that if (6.2) holds, then $\phi$ is singular. Since $\phi$ has bounded variation, its derivative $\phi^{\prime}$ exists almost everywhere [S; Chap. IV. Th. (9.1)] ( $\phi^{\prime}$ may take on the values $+\infty$ and $-\infty$ ). In order to check that $\phi$ is singular, it suffices to show that $\phi^{\prime}=0 \mu_{1}$-a.s. [S; Chap. IV. Th. (7.8)].

Set $N=\left\{u \in[0, \bar{u}]: \phi^{\prime}(u)\right.$ exists and $\left.\phi^{\prime}(u) \neq 0\right\}$. We assume $\mu_{1}(N)>0$ and show that this leads to a contradiction. Now $N=N_{1} \cup N_{2}$, where

$$
N_{1}=\left\{u \in[0, \bar{u}]: \phi^{\prime}(u) \text { exists and }-\infty \leq \phi^{\prime}(u)<0\right\}
$$

and $N_{2}=N \backslash N_{1}$. So we may as well assume $\mu_{1}\left(N_{1}\right)>0$. Now observe that $\mathrm{N}_{1} \subset \mathrm{p}\left(\mathrm{D}_{1}\right)$. To derive a contradiction, we are going to show that for some
$u_{0} \in[0, \bar{u}], \mathrm{f}(\cdot)=l\left(\mathrm{u}_{0}, \cdot\right)$ satisfies $\mathrm{f}^{\prime}=\phi^{\prime}$ on a subset of $\mathrm{N}_{1}$ with positive Lebesgue measure.

Since $p\left(D_{1}\right)$ is a countable union of sets of the form $p\left(R_{k}\right)$, where $R_{k}$ is a rectangle contained in $D_{1}$, there is a rectangle $R \subset D_{1}$ such that $\mu_{1}\left(N_{1} \cap p(R)\right)>0$. Let $a<b$, $c<d$ be such that $R=[a, b] \times[c, d]$, and set $u_{0}=b, f(u)=l\left(u_{0}, u\right), u \geq u_{0}$. Fix $u>u_{0}, u \in N_{1} \cap p(R)$. We show that $f^{\prime}(u)=\phi^{\prime}(u)$. Now since $\phi^{\prime}(u)<0$ and $u \in p(R)$, we must have $f(u)=\phi(u)$. But then, for sufficiently small $h>0$, we have

$$
D(f, h)=\frac{f(u+h)-f(u)}{h} \leq \frac{\phi(u+h)-\phi(u)}{h}
$$

so

$$
\begin{equation*}
\underset{h \downarrow 0}{\limsup } D(f, h) \leq \phi^{\prime}(\mathrm{u}) . \tag{6.3}
\end{equation*}
$$

Now fix $\varepsilon>0$. Then for sufficiently small $h>0$,

$$
\phi(u+h) \geq \phi(u)+h\left(\phi^{\prime}(u)-\varepsilon\right) .
$$

The right-hand side of this inequality is a decreasing function of $h$, so

$$
f(u+h) \geq f(u)+h\left(\phi^{\prime}(u)-\varepsilon\right)
$$

But then

$$
\liminf _{\mathrm{h} \downarrow 0} D(f, h) \geq \phi^{\prime}(\mathrm{u})-\varepsilon
$$

Since $\varepsilon$ is arbitrary, we combine this inequality with (6.3) to get

$$
\lim _{\mathrm{h} \downarrow 0} D(f, h)=\phi^{\prime}(u) .
$$

A similar argument for $h \uparrow 0$ gives $f^{\prime}(u)=\phi^{\prime}(u)<0$.
Thus $\mathrm{f}^{\prime}<0$ on a set of positive Lebesgue measure, so f cannot be singular with respect to $\mu_{1}$. By part (a), this contradicts the assumption that (6.2) holds, and the proof is complete.
