Some extensions of the arc sine law as (partial) consequences of the scaling property of Brownian motion.

Ph. Carmona, F. Petit, M. Yor

Université Paris VI - Laboratoire de Probabilités associé au C.N.R.S. N° 224 - 4, Place Jussieu - Tour 56 - 3<sup>ème</sup> Etage - 75252 PARIS 05

1. Introduction.

(1.1) Let  $(B_t ; t \geq 0)$  be a 1-dimensional motion, starting from 0.

Define  $A_t^+ = \int_0^t ds 1_{(B_s \geq 0)}$  and  $A_t^- = \int_0^t ds 1_{(B_s < 0)}$ .

Lévy ([10], 1939) showed that, for each  $t > 0$ ,  $\frac{1}{t} A^+(t)$  is arc sine distributed, i.e. :

$$(1.a) \quad P\left(\frac{A^+(t)}{t} \in du\right) = \frac{du}{\pi\sqrt{u(1-u)}} \quad (0 < u < 1).$$

On his way to his result, Lévy proved that : for any  $t > 0, s > 0$ ,

$$(1.b) \quad \frac{1}{t} A^+(t) \stackrel{(law)}{=} \frac{A^+(\tau(s))}{\tau(s)} \left( \equiv \frac{A^+(\tau(s))}{A^+(\tau(s)) + A^-(\tau(s))} \right)$$

where  $(\tau(s), s \geq 0)$  denotes the right-continuous inverse of the local time  $(\ell_t, t \geq 0)$  of Brownian motion at 0.

The identity (1.a) is an easy consequence of (1.b) since, by excursion theory,

$(A^+(\tau(s)), s \geq 0)$  and  $(A^-(\tau(s)), s \geq 0)$  are two independent stable  $(\frac{1}{2})$

subordinators, which satisfy :

$$A^+(\tau(s)) \stackrel{(law)}{=} A^-(\tau(s)) \stackrel{(law)}{=} \frac{s^2}{4N^2},$$

where  $N$  is a standard gaussian, centered, reduced variable, so that from (1.b), we obtain :

$$(1.c) \quad \frac{1}{t} A^+(t) \stackrel{(law)}{=} \frac{N_-^2}{N_+^2 + N_-^2},$$

where  $N_+$  and  $N_-$  are two independent copies of  $N$  ; since it is well known that the right-hand side of (1.c) is arc sine distributed, the identity (1.c) implies (1.a).

(1.2) Barlow-Pitman-Yor [2] obtained the following reinforcement of (1.b) : for every fixed  $t > 0$ , and  $s > 0$ ,

$$(1.d) \quad \frac{1}{\ell_t^2} (A^-(t), A^-(t)) \stackrel{(law)}{=} \frac{1}{s^2} (A^+(\tau(s)), A^-(\tau(s))).$$

To see that this is indeed a strenghtening of (1.b), remark that (1.d) is equivalent (by elementary algebraic manipulations) to :

$$(1.d') \quad \frac{1}{t} (A^+(t), \ell_t^2) \stackrel{(law)}{=} \left( \frac{A^+(\tau(s))}{\tau(s)} ; \frac{s^2}{\tau(s)} \right).$$

The proof of (1.d) presented in [2] is done by replacing  $t$  on the left-hand side of (1.d) by  $T$ , an exponential time independent of  $B$ , and using excursion theory. A short summary of this approach is presented in Revuz-Yor ([19], Exercise 2.17, p. 449-450).

A remarkable feature of (1.d) is that the laws of the 2-dimensional functional :

$$F(u) \equiv \frac{1}{\ell_u^2} (A^+(u), A^-(u))$$

taken at a fixed time  $u = t$ , where  $B_t \neq 0$ , a.s., and at time  $u = \tau(s)$ ,

where  $B_{\tau(s)} = 0$ , a.s., are the same. In order to understand better what lies behind this coïncidence, Pitman-Yor [16] and Perman-Pitman-Yor [13] present some infinite dimensional identities (see, e.g., Theorem (1.1) of [16]) which, again, strenghten (1.d) ; in particular, there exists a rearrangement of the trajectory of the pseudo-Brownian bridge (using the terminology in [16]) :

$$\left( \frac{1}{\sqrt{\tau_1}} B_{u\tau_1} ; u \leq 1 \right)$$

from which the law of  $(B_t ; t \leq g)$ , where  $g \equiv \sup\{t < 1 : B_t = 0\}$ , is recovered (see [16], Theorem 1.3, and [13], Theorem 3.8).

(1.3) Brownian excursion theory plays an essential part in the proofs given in [16] and [13], and, as a consequence, it seemed a quite difficult task to modify the arguments of [16] and [13] to prove the following variant of (1.d), which is due to the second author ([14], [15]) : let  $\mu > 0$ , and  $t > 0, s > 0$  ; then, the identity in law

$$(1.e) \quad \frac{1}{(\ell_t^{(\mu)})^2} (A^{\mu,+}(t), A^{\mu,-}(t)) \stackrel{(law)}{=} \frac{1}{s^2} (A^{\mu,+}(\tau^\mu(s)), A^{\mu,-}(\tau^\mu(s)))$$

$$\text{where } A^{\mu,\pm}(t) = \int_0^t ds \mathbb{1}_{(|B_s| - \mu \ell_s \in \mathbb{R}_\pm)},$$

$(\ell_t^{(\mu)}, t \geq 0)$  denotes the local time at 0 of  $(|B_t| - \mu \ell_t ; t \geq 0)$ , and  $(\tau^\mu(s), s \geq 0)$  is the right-continuous inverse of  $(\ell_t^{(\mu)} ; t \geq 0)$ .

As explained in [15] and [23], but only partly proven, both sides of (1.e) are distributed as :

$$(1.f) \quad \frac{1}{8} \left( \frac{1}{Z_{1/2}}, \frac{1}{Z_{1/2\mu}} \right)$$

where, here, and in the sequel,  $Z_a$  will denote a gamma variable with parameter  $a$ , i.e :

$$P(Z_a \in dt) = dt t^{a-1} e^{-t} \quad (t > 0)$$

and the two gamma variables featured in (1.f) are independent.

The following extension of Lévy's arc sine law (1.a) is a consequence of the identity in law between the variables in (1.e) and (1.f) :

$$(1.g) \quad A_1^{\mu,-} \stackrel{\text{(law)}}{=} Z_{1/2,1/2\mu},$$

where  $Z_{a,b}$  denotes a beta variable with parameters  $a$  and  $b$ , i.e.

$$P(Z_{a,b} \in dt) = \frac{dt}{B(a,b)} t^{a-1}(1-t)^{b-1} dt \quad (0 < t < 1)$$

(1.4) A few words of explanation may be in order concerning our interest in the variables  $A^{\mu,\pm}(t)$ : it was found in [8] that the random variables

$$A^{\mu,\pm}(\tau(1)) \equiv \int_0^{\tau(1)} ds \mathbf{1}_{(|B_s| - \mu \ell_s \in \mathbb{R}_{\pm})}$$

play an important role in the

expressions of the limits in law of the winding numbers of 3-dimensional Brownian motion around curves going to infinity in  $\mathbb{R}^3$ ; henceforth, it seemed natural to study the distributions of  $A^{\mu,\pm}(t)$ , for fixed time  $t$ . We now remark that these random variables occur similarly as the limits in law for two families of natural quantities related to 1-dimensional Brownian motion  $(B_t; t \geq 0)$ :

(a) let  $f: \mathbb{R} \rightarrow \mathbb{R}$  be an integrable function, and define:

$$F(t) = \int_0^t du f(B_u), \text{ and } A_t^f = \int_0^t ds \mathbf{1}_{(|B_s| \geq F(s))}.$$

Then, denoting:  $\bar{f} = \int_{-\infty}^{+\infty} dx f(x)$ , it is not difficult to prove:

$$(1.h) \quad \frac{1}{t} A_t^f \stackrel{\text{(law)}}{t \rightarrow \infty} A_1^{\bar{f},+} \equiv \int_0^1 du \mathbf{1}_{(|B_u| \geq \bar{f} \ell_u)}.$$

Indeed, using the scaling property of  $B$ , and the occupation time density formula, we have:

$$\frac{1}{t} A_t^f \stackrel{(law)}{=} \int_0^1 du \mathbb{1}_{\left(|B_u| \geq \sqrt{t} \int_0^u dh f(\sqrt{t} B_h)\right)}$$

$$\stackrel{(law)}{=} \int_0^1 du \mathbb{1}_{\left(|B_u| \geq \int dx f(x) \ell_u^{x/\sqrt{t}}\right)}$$

and we obtain (1.h) by letting  $t \rightarrow \infty$ .

We remark that, in the case  $\bar{f} = 1$ , which occurs in particular when  $f$  is a probability density, the right-hand side of (1.h) is arc-sine distributed, since  $(|B_u| - \ell_u; u \geq 0)$  is a Brownian motion.

(b) The random variables  $A^{\mu, \pm}(1)$  also occur as limits in law of the following random variables :

$$\frac{1}{t} E_t^{(\alpha)} \stackrel{\text{def}}{=} \frac{1}{t} \int_0^t ds \mathbb{1}_{\left\{\exp(B_s) \geq \left(\frac{1}{s} \int_0^s du \exp B_u\right)^\alpha\right\}}$$

which represents the fraction of time spent by the geometric Brownian motion  $\{\exp(B_s), s \leq t\}$  above the  $\alpha^{\text{th}}$ -power of its average ; we now prove :

$$(1.i) \quad \frac{1}{t} E_t^{(\alpha)} \xrightarrow[t \rightarrow \infty]{(law)} A_1^{\bar{\alpha}, -} \equiv \int_0^1 du \mathbb{1}_{(|B_u| \leq \bar{\alpha} \ell_u)} \quad , \quad \text{where } \bar{\alpha} = 1 - \alpha.$$

(Obviously, in the case  $\alpha \geq 1$ , the right-hand side of (1.i) is equal to 0).

To prove (1.i), we remark that :

$$\frac{1}{t} E_t^{(\alpha)} \stackrel{(law)}{=} \int_0^1 du \mathbb{1}_{\left(B_u \geq \frac{\alpha}{\sqrt{t}} \log \left(\frac{1}{u} \int_0^u dh \exp(\sqrt{t} B_h)\right)\right)}$$

and the right-hand side converges in law, as  $t \rightarrow \infty$ , towards :

$$\int_0^1 du \mathbf{1}_{(B_u \geq \alpha S_u)} \quad , \quad \text{where } S_u = \sup_{s \leq u} B_s.$$

Now, using Lévy's equivalence :  $(|B_u|, \ell_u ; u \geq 0) \stackrel{(law)}{=} (S_u - B_u, S_u ; u \geq 0)$  ,  
we obtain :

$$\int_0^1 du \mathbf{1}_{(B_u \geq \alpha S_u)} \stackrel{(law)}{=} \int_0^1 du \mathbf{1}_{(|B_u| \leq \bar{\alpha} \ell_u)} ,$$

which finishes the proof of (1.i).

(1.5) The main objective of this paper is to give a simple proof of the identity in law (1.e), relying essentially on Brownian scaling arguments, and on the independence of the processes

$$(A^{\mu,+}(\tau^\mu(s)), s \geq 0) \quad \text{and} \quad (A^{\mu,-}(\tau^\mu(s)), s \geq 0).$$

This will be done in the third section of this paper, by modifying and developing some of the arguments of D. Williams [22], involving the process  $\alpha_t^+ \equiv \inf\{u : A_u^+ > t\}$  ; for the reader's convenience, such modifications will be first presented in the second section of the paper, in order to derive (1.d) independently of the arguments of Barlow-Pitman-Yor [2] and Pitman-Yor [16].

To keep this introduction reasonably short, we briefly recall here that D. Williams' proof of the arc sine law (1.a) relies upon the identity :

$$(1.j) \quad \alpha_t^+ = t + A^-(\alpha^+(t)) \equiv t + A_\tau^-(\ell_{\alpha^+(t)}^+) , \quad t \geq 0, \quad (*)$$

and on the essential fact that the processes :

---

(\*) For notational convenience, we shall write sometimes  $(A_\tau^-(u), u \geq 0)$  or  $(A^-(\tau(u)), u \geq 0)$  for the process  $(A_{\tau(u)}^-, u \geq 0)$ , and similarly for  $A^+$ , and  $A^{\mu,\pm}$ .

(1.k)  $(A^-(\tau(u)), u \geq 0)$  and  $(\ell_{\alpha^+(t)}, t \geq 0) \equiv ((A_t^+)^{-1}(t), t \geq 0)$   
*are independent.*

This approach is detailed in Karatzas-Shreve [7], but, strangely enough, perhaps due to its apparent asymmetry, it is not discussed in either [2] or [16], in relation with (1.d).

In section 4, we develop some studies related to the process  $(X_t = |B_t| - \mu \ell_t; t \geq 0)$ ; in particular, we compare the law of  $(X_t, t \leq 1)$ , conditioned by  $X_1 = 0$ , to those of  $\left(\frac{1}{\sqrt{\tau_1^\mu}} X_{t\tau_1^\mu}; t \leq 1\right)$  and of  $\left(\frac{1}{\sqrt{g_1^\mu}} X_{tg_1^\mu}; t \leq 1\right)$ , where  $g_1^\mu = \sup\{s < 1 : X_s = 0\}$ .

The first result is obtained just as in the Brownian case ( $\mu=1$ ), but the second is quite different, and seems to necessitate some involved computations.

In section 5, we show how the proof of (1.d) can be modified to obtain, in a similar way as above, some multidimensional extension of the arc sine law for Walsh's Brownian motions and Bessel processes taking values in  $n$  rays in the plane; the original result, which is the identity (5.a) below, was also obtained in [2].

(1.6) Our incentive to develop thoroughly these various extensions of (1.d) has two origins :

- the first origin is that, as explained in (1.3) above, we wanted to give a simple explanation of the identity in law between the left-hand side of (1.e), and (1.f) ;
- the second origin is the result recently obtained by S. Watanabe [21] that the distributions featured in [2], for the time spent in  $\mathbb{R}_+$  by a skew Bessel process, are essentially the only possible limits in law, as  $t \rightarrow \infty$ , of the quantities :

$$\frac{1}{t} A_t \equiv \frac{1}{t} \int_0^t ds 1_{(X_s > 0)},$$

where  $X$  is a generalized diffusion. To be precise, these distributions are the laws of the following ratios :

$$(1.l) \quad \frac{p^{1/\mu} T}{p^{1/\mu} T + q^{1/\mu} T'}$$

where  $0 < \mu < 1$ ,  $p + q = 1$ , and  $T$  and  $T'$  are two independent, one-sided stable variables, with index  $\mu$ . (J. Lamperti showed that the variables in (1.l) have a simple enough density ; see, e.g., [16] p. 343).

## 2. D. Williams' proof of the arc sine law and the identity (1.d).

(2.1) To begin with, we show how, using (1.j) and scaling arguments, one deduces (1.b) ; this is also presented succinctly in [23], p. 104-105.

We remark that, from (1.j) and (1.k), we have, by scaling :

$$\alpha_1^+ \stackrel{(law)}{\equiv} 1 + \left( \frac{\ell^2}{\alpha_1^+} \right) (A^-(\tau(1))) \stackrel{(law)}{\equiv} 1 + \frac{A^-(\tau(1))}{A^+(\tau(1))} \equiv \frac{\tau(1)}{A^+(\tau(1))}$$

and, finally, again by scaling :

$$A_1^+ \stackrel{(law)}{\equiv} \frac{1}{\alpha_1^+} \stackrel{(law)}{\equiv} \frac{A^+(\tau(1))}{\tau(1)}$$

which proves (1.b).

(2.2) Bootstrapping on the previous arguments, we shall prove the identity (1.d), as a consequence of the following

**Proposition 2.1** : *Let  $F : C[0,1] \rightarrow \mathbb{R}_+$  be a measurable functional. Then, we have :*

$$(2.a) \quad E \left[ F(B_u ; u \leq 1) 1_{(B_1 > 0)} \right] = E \left[ F \left( \frac{1}{\sqrt{\alpha_1^+}} B_{s\alpha_1^+} ; s \leq 1 \right) \frac{1}{\alpha_1^+} \right].$$

Proof : Let  $T$  be an  $\mathbb{R}_+$ -valued random time, which is independent of  $B$ , and

whose law is given by :  $P(T \in dt) = h(t)dt$ ,

for some probability density  $h$  (e.g. :  $h(t) = \exp(-t)$ , but any probability density will do). Then, we have :

$$\begin{aligned}
E\left[F(B_u ; u \leq 1) 1_{(B_1 > 0)}\right] &= E\left[F\left(\frac{1}{\sqrt{T}} B_{uT} ; u \leq 1\right) 1_{(B_T > 0)}\right] \\
&= \int_0^{+\infty} dt h(t) E\left[1_{(B_t > 0)} F\left(\frac{1}{\sqrt{t}} B_{st} ; s \leq 1\right)\right] \\
&= E\left[\int_0^{+\infty} dA_t^+ h(t) F\left(\frac{1}{\sqrt{t}} B_{ut} ; u \leq 1\right)\right] \\
&= E\left[\int_0^{+\infty} du h(\alpha_u^+) F\left(\frac{1}{\sqrt{\alpha_u^+}} B_{s\alpha_u^+} ; s \leq 1\right)\right] \\
&= \int_0^{+\infty} du E\left[h(u\alpha_1^+) F\left(\frac{1}{\sqrt{\alpha_1^+}} B_{s\alpha_1^+} ; s \leq 1\right)\right] && \text{(by scaling)} \\
&= E\left[\frac{1}{\alpha_1^+} \left(\int_0^{+\infty} dv h(v)\right) F\left(\frac{1}{\sqrt{\alpha_1^+}} B_{s\alpha_1^+} ; s \leq 1\right)\right] && \text{(taking : } v = u\alpha_1^+) \\
&= E\left[\frac{1}{\alpha_1^+} F\left(\frac{1}{\sqrt{\alpha_1^+}} B_{s\alpha_1^+} ; s \leq 1\right)\right] \quad \text{(since } h \text{ is a probability density).} \quad \square
\end{aligned}$$

**Corollary 2.1.1** : (i) Let  $f : \mathbb{R}_+ \times \mathbb{R}_+ \longrightarrow \mathbb{R}_+$  be a Borel function ; then :

$$(2.b)_+ \quad E\left[f\left(\frac{A_1^+, A_1^-}{\ell_1^2}\right) 1_{(B_1 > 0)}\right] = E\left[\frac{A^+(\tau(1))}{\tau(1)} (A_{\tau(1)}^+, A_{\tau(1)}^-)\right].$$

(ii) The identity in law

$$(1.d) \quad \frac{1}{\ell_1^2} (A_1^+, A_1^-) \stackrel{(\text{law})}{=} (A^+(\tau(1)), A^-(\tau(1)))$$

holds ;

$$(iii) \quad P(B_1 > 0 | A_1^+ = a, \ell_1) = a.$$

Proof : (i) From (2.a), the left-hand side of (2.b)<sub>+</sub> is equal to :

$$\begin{aligned} & E \left[ \frac{1}{\alpha_1^+} f \left( \frac{1}{\ell_{\alpha_1^+}^2} ; \frac{A_{\alpha_1^+}^-(1)}{\ell_{\alpha_1^+}^2} \right) \right] \\ &= E \left[ \frac{1}{1+A_{\tau}^-(\ell_{\alpha_1^+}(1))} f \left( \frac{1}{\ell_{\alpha_1^+}^2} ; \frac{A_{\tau}^-(\ell_{\alpha_1^+}(1))}{\ell_{\alpha_1^+}^2} \right) \right] \quad (\text{from (1.j)}). \end{aligned}$$

Using the same scaling arguments as in subsection (2.1), we find that the last written quantity is equal to the right-hand side of (2.b)<sub>+</sub>.

(ii) Replacing B by -B in (2.b)<sub>+</sub>, we also obtain :

$$(2.b)_- \quad E \left[ f \left( \frac{A_1^+, A_1^-}{\ell_1^2} \right) 1_{(B_1 < 0)} \right] = E \left[ \frac{A^-(\tau(1))}{\tau(1)} f(A_{\tau(1)}^+, A_{\tau(1)}^-) \right],$$

so that, adding (2.b)<sub>+</sub> and (2.b)<sub>-</sub>, we obtain :

$$E \left[ f \left( \frac{A_1^+, A_1^-}{\ell_1^2} \right) \right] = E[f(A_{\tau(1)}^+, A_{\tau(1)}^-)],$$

which is equivalent to (1.d).

(iii) Making use jointly of (2.b)<sub>+</sub> and (1.d), we obtain :

$$E \left[ f \left( \frac{A_1^+, A_1^-}{\ell_1^2} \right) \frac{1_{(B_1 > 0)}}{A_1^+} \right] = E[f(A_{\tau(1)}^+, A_{\tau(1)}^-)] = E \left[ f \left( \frac{A_1^+, A_1^-}{\ell_1^2} \right) \right],$$

so that :  $P(B_1 > 0 | A_1^+, \ell_1) = A_1^+.$  □

If we use, together with the identity (2.a), the well-known result :

(2.c)  $(B_{\alpha^+}(t), t \geq 0)$  is a reflecting Brownian motion,

(see, e.g. : Mc Kean [11], Karatzas-Shreve [7],...),

we obtain the following description of the joint law of  $(A_1^+, \ell_1, B_1)$ , which, as the reader may easily check, agrees with the formula given by Karatzas-Shreve ([7], p. 423).

**Corollary 2.1.2** : We use the notation :  $A_1^\varepsilon = A_1^+$ , if  $B_1 > 0$  ;  $A_1^\varepsilon = A_1^-$ , if  $B_1 < 0$ .

Then, we have for every Borel  $g : \mathbb{R}_+ \longrightarrow \mathbb{R}_+$ , and  $a_+, a_- \geq 0$  :

$$E \left[ g \left( \frac{|B_1|}{(A_1^\varepsilon)^{1/2}} \right) \middle| \frac{A_1^+}{\ell_1^2} = a_+, \frac{A_1^-}{\ell_1^2} = a_- \right]$$

(2.d)

$$= \left( \frac{a_+}{a_+ + a_-} \right) E \left[ g(|B_1|) \middle| \ell_1 = \frac{1}{2\sqrt{a_+}} \right] + \frac{a_-}{a_+ + a_-} E \left[ g(|B_1|) \middle| \ell_1 = \frac{1}{2\sqrt{a_-}} \right].$$

Proof : a) Let  $f : \mathbb{R}_+ \times \mathbb{R}_+ \longrightarrow \mathbb{R}_+$ , and  $g : \mathbb{R}_+ \longrightarrow \mathbb{R}_+$  be two Borel functions. Then, we have, from formula (2.a) :

$$\begin{aligned} E \left[ 1_{(B_1 > 0)} f \left( \frac{(A_1^+, A_1^-)}{\ell_1^2} \right) g \left( \frac{B_1}{(A_1^+)^{1/2}} \right) \right] &= E \left[ \frac{1}{\alpha_1^+} f \left( \frac{(1, A_{\alpha^+}(1))}{\ell_{\alpha^+}^2} \right) g(B_{\alpha^+}(1)) \right] \\ &= E \left[ \frac{1}{(1 + A_{\alpha^+}(1))} f \left( \frac{(1, A_{\alpha^+}(1))}{\ell_{\alpha^+}^2} \right) g(B_{\alpha^+}(1)) \right] \end{aligned}$$

$$\begin{aligned}
&= E \left[ \frac{1}{1+A^-(\tau(\ell_{\alpha_1^+}))} f \left( \frac{(1, A_{\alpha_1^+}^-)}{\ell_{\alpha_1^+}^2} \right) g(B_{\alpha_1^+}) \right] \\
(2.e) \quad &= E \left[ \frac{1}{1+(\ell_{\alpha_1^+}^2)(A^-(\tau(1)))} f \left( \frac{1}{\ell_{\alpha_1^+}^2} ; A^-(\tau(1)) \right) g(B_{\alpha_1^+}) \right] \text{ (by scaling)} \\
(2.f) \quad &= E \left[ \frac{1}{(1+\ell_1^2 T^-)} f \left( \frac{1}{4\ell_1^2} ; \frac{1}{4} T^- \right) g(|B_1|) \right]
\end{aligned}$$

where, for the last two equalities,  $4A^-(\tau(1)) \stackrel{(\text{law})}{=} T^-$  denotes a standard one-sided stable  $(\frac{1}{2})$  variable, which is independent of the reflecting Brownian motion  $(B_{\alpha_1^+(t)}, t \geq 0)$  in (2.e), and of the pair  $(|B_1|, \ell_1)$  in (2.f).

To justify the last equality, we have used (2.c).

b) By symmetry, we may now write :

$$\begin{aligned}
&E \left[ f \left( \frac{(A_1^+, A_1^-)}{\ell_1^2} \right) g \left( \frac{|B_1|}{(A_1^\varepsilon)^{1/2}} \right) \right] \\
(2.g) \quad &= E \left[ \frac{\tilde{\ell}_1^2}{(\ell_1^2 + \tilde{\ell}_1^2)} f \left( \frac{1}{4\ell_1^2}, \frac{1}{4\tilde{\ell}_1^2} \right) g(|B_1|) \right] + E \left[ \frac{\ell_1^2}{(\ell_1^2 + \tilde{\ell}_1^2)} f \left( \frac{1}{4\ell_1^2}, \frac{1}{4\tilde{\ell}_1^2} \right) g(|\tilde{B}_1|) \right],
\end{aligned}$$

where  $B$  and  $\tilde{B}$  denote two independent 1-dimensional Brownian motions, and  $\ell$  and  $\tilde{\ell}$  their respective local times at 0.

The identity (2.d) now follows easily from (2.g).  $\square$

### 3. Some extensions of the arc sine law to perturbed reflecting Brownian motion.

(3.1) Some notation. Throughout this section,  $\mu$  will denote a fixed positive real, and  $(X_t = |B_t| - \mu \ell_t ; t \geq 0)$  is the reflecting Brownian motion

$(|B_t|, t \geq 0)$  perturbed by the subtraction of  $\mu$  times the local time of  $B$  at 0.

As announced in the Introduction, we are interested in the computation of the distribution of :

$$A_t^{\mu,+} \stackrel{\text{def}}{=} \int_0^t ds 1_{(X_s > 0)},$$

and, as above, the local time  $(\ell_t^{(\mu)}, t \geq 0)$  of  $X$  at 0 will play an important role, together with its right continuous inverse  $(\tau^\mu(s), s \geq 0)$ .

(3.2) The methodology of the proof of (1.e) which is adopted here is the same as that of (1.d), developed in Section 2 above. However, in order to make this methodology effective, we first need to describe some essential properties of the 2-dimensional process  $\{A^{\mu,+}(\tau^\mu(s)), A^{\mu,-}(\tau^\mu(s)) ; s \geq 0\}$ .

**Proposition 3.1** : (i) The processes  $(A^{\mu,+}(\tau^\mu(s)), s \geq 0)$  and  $(A^{\mu,-}(\tau^\mu(s)), s \geq 0)$  are independent ;

(ii) For every  $\lambda > 0$ , one has :

$$(A^{\mu,\pm}(\tau^\mu(\lambda s)), s \geq 0) \stackrel{(law)}{=} (\lambda^2 A^{\mu,\pm}(\tau^\mu(s)), s \geq 0)$$

(iii) For every  $s > 0$ , one has :

$$\frac{1}{s^2} A^{\mu,+}(\tau^\mu(s)) \stackrel{(law)}{=} \frac{1}{8Z_{1/2}} \quad \text{and} \quad \frac{1}{s^2} A^{\mu,-}(\tau^\mu(s)) \stackrel{(law)}{=} \frac{1}{8Z_{1/2\mu}}.$$

**Proof** : (i) This independence result is a particular consequence of the more general statement made in Theorem 3.2 below.

(ii) This point follows immediately from the scaling property of  $B$ .

(iii) This is proven in Chapter 9 of [23], Theorem 9.1 and Corollary 9.1.1. ; this Theorem 9.1 is a Ray-Knight theorem for the local times of  $X$  considered up to time  $\tau_s^\mu$  ; a generalized version of it is presented in Theorem 3.3. below.  $\square$

It should now be clear to the reader that the main identities of Section 2 extend when  $B$  is replaced by  $X$ ,  $\alpha^+$  by  $\alpha^{\mu,+}$ ,  $\tau$  by  $\tau^\mu$ , and so on ; in particular, we have :

- the  $\mu$ -variant of (2.a) :

$$(3.a) \quad E \left[ F(X_u ; u \leq 1) 1_{(X_1 > 0)} \right] = E \left[ F \left( \frac{1}{\sqrt{\alpha_1^{\mu,+}}} X_{s\alpha_1^{\mu,+}} ; s \leq 1 \right) \frac{1}{\alpha_1^{\mu,+}} \right]$$

- the  $\mu$ -variant of (2.b)<sub>+</sub> :

$$(3.b)_+ \quad E \left[ f \left( \frac{A_1^{\mu,+}, A_1^{\mu,-}}{(\ell_1^{(\mu)})^2} \right) 1_{(X_1 > 0)} \right] = E \left[ \frac{A_1^{\mu,+}(\tau^\mu(1))}{\tau^\mu(1)} f \left( \frac{A^{\mu,+}}{\tau^\mu(1)}, \frac{A^{\mu,-}}{\tau^\mu(1)} \right) \right]$$

- the  $\mu$ -variant of (1.d) : for  $t > 0$ , and  $s > 0$ ,

$$(1.e) \quad \frac{1}{(\ell_t^{(\mu)})^2} (A_t^{\mu,+}, A_t^{\mu,-}) \stackrel{\text{(law)}}{=} \frac{1}{s^2} (A^{\mu,+}(\tau^\mu(s)), A^{\mu,-}(\tau^\mu(s))).$$

from which we deduce (1.f) and (1.g), thanks to Proposition 3.1.

- the  $\mu$ -variant of point (iii) in Corollary 2.1.1 :

$$(3.c) \quad P(X_1 > 0 | A^{\mu,+} = a, \ell_1^{(\mu)} = a)$$

(3.3) We now complete the proof of Proposition 3.1 by showing the more general

Theorem 3.2 : For  $t \geq 0$ , define  $\left\{L_t^+ = (\ell_{\tau_t^\mu}^{(\mu),x} ; x \geq 0) ; t \geq 0\right\}$

and  $\left\{L_t^- = (\ell_{\tau_t^\mu}^{(\mu),-x} ; x \geq 0) ; t \geq 0\right\}$  two continuous processes [as functions

of  $t \geq 0$ ] taking their values in the space  $\Sigma = C_c(\mathbb{R}_+, \mathbb{R}_+)$  of continuous

functions  $f : \mathbb{R}_+ \rightarrow \mathbb{R}_+$  with compact support. Then

(i) the processes  $(L_t^+ ; t \geq 0)$  and  $(L_t^- ; t \geq 0)$  are independent ;

(ii) each of them is an homogeneous Markov process ;

(iii) the process  $(L_t^+ ; t \geq 0)$  has independent increments, and for each  $t > 0$ , the distribution of the variable  $L_t^+$  is  $Q_t^0$ , the law of the square of a 0-dimensional Bessel process starting from  $t$ .

Proof : 1) We first remark that  $(\ell_t^{(\mu)} ; t \geq 0)$  is an additive functional of the 2-dimensional Markov process  $\{\tilde{B}_t \equiv (|B_t|, \ell_t) ; t \geq 0\}$  ; as a consequence, the process  $(\hat{B}_t \stackrel{\text{def}}{=} \tilde{B}_{\tau_t^\mu} ; t \geq 0)$  is also an homogeneous Markov process ; we

then remark that the two components of  $\hat{B}_t$ , namely :  $|B_{\tau_t^\mu}|$  and  $\ell_{\tau_t^\mu}$  are

related by :  $|B_{\tau_t^\mu}| = \mu \ell_{\tau_t^\mu}$  ; hence, the process  $(|B_{\tau_t^\mu}| ; t \geq 0)$  is itself

an homogeneous Markov process ; since  $-\mu \ell_{\tau_t^\mu} = \inf_{s \leq \tau_t^\mu} X_s$ , the r.v.  $|B_{\tau_t^\mu}|$  is

measurable with respect to the  $\sigma$ -field generated by  $L_t^-$ .

The same arguments prove that  $(L_t \equiv (L_t^+, L_t^-) ; t \geq 0)$  is an homogeneous Markov process. Moreover, since, for every  $t$ ,  $|B_{\tau_t^\mu}|$  is measurable with res-

pect to  $\sigma(L_t^-)$ , it is obvious that  $L^- \equiv (L_t^-; t \geq 0)$  is, by itself, an homogeneous Markov process.

2) We now proceed to the proof of the independence of the processes  $(L_t^+; t \geq 0)$  and  $(L_t^-; t \geq 0)$ ; this will be obtained from a recurrence argument bearing upon the dimension  $k$  of the marginals  $(L_{t_1}^+, \dots, L_{t_k}^+)$  and  $(L_{t_1}^-, \dots, L_{t_k}^-)$  for  $t_1 < t_2 < \dots < t_k$ , of the processes  $(L_t^+; t \geq 0)$  and  $(L_t^-; t \geq 0)$ .

- first, we already know, for  $k = 1$ , by Theorem 9.1 in [23], that for a given  $t_1 \equiv t > 0$ ,  $L_t^+$  and  $L_t^-$  are independent;

- next, we assume that, for  $t_1 < t_2 < \dots < t_{k-1} < t_k$ , the  $(k-1)$  dimensional marginals  $(L_{t_1}^+, \dots, L_{t_{k-1}}^+)$  and  $(L_{t_1}^-, \dots, L_{t_{k-1}}^-)$  are independent.

Then, we know, from the Markov property of the process  $((L_t^+, L_t^-); t \geq 0)$ , that for any measurable  $F : \Sigma \times \Sigma \rightarrow \mathbb{R}_+$ :

$$E\left[F(L_{t_k}^+, L_{t_k}^-) \mid \sigma\{L_s; s \leq t_{k-1}\}\right] = E\left[F(L_{t_k}^+, L_{t_k}^-) \mid L_{t_{k-1}}^+, L_{t_{k-1}}^-\right],$$

so that, to finish the recurrence argument, it remains to prove that for two positive reals  $s < t$ ,

the pairs  $(L_s^+, L_t^+)$  and  $(L_s^-, L_t^-)$  are independent,

or, equivalently, for  $F_i(\ell) \equiv \exp(-\langle \ell, \varphi_i \rangle)$  and  $G_i(\ell) \equiv \exp(-\langle \ell, \psi_i \rangle)$ ,  $i = 1, 2$ ,

where  $\{\varphi_i, \psi_i; i = 1, 2\}$  are four continuous functions with compact support

on  $\mathbb{R}_+$ , and  $\langle \ell, f \rangle = \int_0^{+\infty} dx \ell^x f(x)$ , we have :

$$(3.d) \quad E[F_1(L_s^+)G_1(L_s^-)F_2(L_t^+)G_2(L_t^-)] = E[F_1(L_s^+)F_2(L_t^+)E[G_1(L_s^-)G_2(L_t^-)]].$$

The left-hand side of (3.d) is equal to :

$$\begin{aligned}
& E[\exp\{-\langle L_s^+, \varphi_1 \rangle - \langle L_s^-, \psi_1 \rangle - \langle L_t^+, \varphi_1 \rangle - \langle L_t^-, \psi_2 \rangle\}] \\
&= E[\exp\{-\langle L_s^+, \varphi_1 + \varphi_2 \rangle - \langle L_s^-, \psi_1 + \psi_2 \rangle\} E_{\hat{B}_s}(\exp\{-\langle L_{t-s}^+, \varphi_2 \rangle - \langle L_{t-s}^-, \psi_2 \rangle\})] \\
&\quad \text{(from the Markov property for } (L_t, t \geq 0)) \\
&= E[\exp(-\langle L_s^+ ; \varphi_1 + \varphi_2 \rangle)] E[\exp(-\langle L_s^- ; \psi_1 + \psi_2 \rangle) E_{\hat{B}_s}(\exp\{-\langle L_{t-s}^+, \varphi_2 \rangle - \langle L_{t-s}^-, \psi_2 \rangle\})]
\end{aligned}$$

from the independence of  $L_s^+$  and  $L_s^-$ , and the fact that  $\hat{B}_s$  is measurable with respect to  $\sigma(L_s^-)$ .

It is now clear that the identity (3.d) will be proven, together with the independence and the homogeneity of the increments of the process  $(L_t^+ ; t \geq 0)$  if we show :

$$\begin{aligned}
& E_{\hat{B}_s}(\exp\{-\langle L_{t-s}^+, \varphi_2 \rangle - \langle L_{t-s}^-, \psi_2 \rangle\}) \\
(3.e) \quad &= E[\exp(-\langle L_{t-s}^+, \varphi_2 \rangle)] E_{\hat{B}_s}[\exp(-\langle L_{t-s}^-, \psi_2 \rangle)].
\end{aligned}$$

In (3.e), the notation  $E_{\hat{B}_s}$  refers to the family of distributions of the Markov process  $(|B_t|, \ell_t ; t \geq 0)$  starting from  $(a, \xi)$  with, furthermore :

$$a = |B_{\tau_s^\mu}|, \quad \text{and} \quad \xi = \ell_{\tau_s^\mu} = \frac{a}{\mu}.$$

Since  $(\ell_t, t \geq 0)$  is an additive functional of  $(|B_t|, t \geq 0)$ , we have, in general :

$$E_{a, \xi}[F(|B_t|, \ell_t ; t \geq 0)] = E_a[F(|B_t|, \ell_t + \xi ; t \geq 0)],$$

where  $P_a$  is now simply the distribution of  $(|B_t|, t \geq 0)$ , starting from  $a$

(and, in (3.e),  $E$  refers to  $P_0$ ).

Once this notation has been made precise, we remark that :

$$(3.f) \quad E_{a, \frac{a}{\mu}} [\exp\{-\langle L_{t-s}^+, \varphi_2 \rangle - \langle L_{t-s}^-, \psi_2 \rangle\}] = E_a [\exp\{-\langle L_{t-s}^{a,+}, \varphi_2 \rangle - \langle L_{t-s}^{a,-}, \psi_2 \rangle\}]$$

where :

$$(3.g) \quad L_t^{a,+} \equiv (\ell_{\tau_t^{\mu,a}}^{\mu, a+x} ; x \geq 0) ; L_t^{a,-} \equiv (\ell_{\tau_t^{\mu,a}}^{\mu, a-x} ; x \geq 0).$$

Here,  $(\ell_u^{\mu,y} ; u \geq 0)$  denotes the local time at level  $y$  of the process  $(X_u \equiv |B_u| - \mu \ell_u ; u \geq 0)$ , while  $(\tau_t^{\mu,a} ; t \geq 0)$  is the right continuous inverse of  $(\ell_u^{\mu,a} ; u \geq 0)$ .

It now follows from the Ray-Knight theorem stated as Theorem 3.3. below that the right-hand side of (3.f) is equal to :

$$\begin{aligned} & E_a \left[ \exp\left\{-\langle L_{t-s}^{a,+}, \varphi_2 \rangle\right\} \right] E_a \left[ \exp\left\{-\langle L_{t-s}^{a,-}, \psi_2 \rangle\right\} \right] \\ &= E \left[ \exp\left\{-\langle L_{t-s}^+, \varphi_2 \rangle\right\} \right] E_a \left[ \exp\left\{-\langle L_{t-s}^{a,-}, \psi_2 \rangle\right\} \right], \end{aligned}$$

which proves (3.e). □

In order to complete the above proof, we state a Ray-Knight theorem which describes the law of the local times processes in (3.g) ; this theorem generalizes Theorem 9.1 in [23], with an analogous proof ; hence, details will not be reproduced.

**Theorem 3.3** : *Let  $a \geq 0$ , and  $t > 0$  be fixed.*

*Consider  $(|B_t|, t \geq 0)$  a reflecting Brownian motion starting from  $a$ , and*

$(\ell_{\tau_t^{\mu,a}}^{\mu,x} ; x \in \mathbb{R})$  the family of local times of  $(X_u \equiv |B_u| - \mu \ell_u ; u \geq 0)$ ,

considered at time  $\tau_t^{\mu,a} \equiv \inf\{u : \ell_u^{\mu,a} > t\}$ . Then :

(i) the two processes  $L_t^{a,+} \equiv (\ell_{\tau_t^{\mu,a}}^{\mu,x+a} ; x \geq 0)$  and  $L_t^{a,-} \equiv (\ell_{\tau_t^{\mu,a}}^{\mu,a-x} ; x \geq 0)$

are independent ;

(ii)  $L_t^{a,+}$  is, as a process in  $x \geq 0$ , a  $BESQ_t^0$ , that is : the square starting at  $t$ , of a 0-dimensional Bessel process ;

(iii)  $L_t^{a,-}$  is, as a process in  $x \geq 0$ , an inhomogeneous Markov process, which is a  $BESQ_t^0$  on the  $x$ -interval  $[0,a]$ , and a  $BESQ_{2-\frac{2}{\mu}}$  process on  $[a,\infty[$ ; both processes are absorbed at 0.

**Important remark** : Theorem 3.3 extends, for all  $\mu > 0$ , the two main Ray-Knight theorems known for Brownian local times ( $\mu = 1$ ) and, moreover, it allows to unify their statements, with the introduction of the stopping times  $\tau_t^{\mu,a}$ . To see this, we recall these two theorems (see, e.g., [19], Chapter 11, paragraph 2), by referring ourselves to particular cases considered in Theorem 3.3 :

$\alpha$ ) if we take  $\mu = 1$ , and  $a = 0$ , then  $L_t^{0,+}$  and  $L_t^{0,-}$  are two independent  $BESQ_t^0$  processes indexed by  $x \in \mathbb{R}_+$  ;

$\beta$ ) if we take  $\mu = 1$ ,  $t = 0$ , and  $a > 0$ , then :  $\tau_0^{1,a} \equiv \inf\{t : |B_t| - \ell_t = a\}$  is the first hitting time of  $a$  by the 1-dimensional Brownian motion  $\{|B_t| - \ell_t ; t \geq 0\}$  and, from (iii) above,  $L_0^{a,-}$  is, as a process in  $x \geq 0$ , an inhomogeneous Markov process which is a  $BESQ_0^2$  on the  $x$ -interval  $[0,a]$ , and a  $BESQ^0$  on  $[a,\infty[$ .  $\square$

Independently of its interest for the proof of Theorem 3.2, we will use Theorem 3.3 in section 4 for the proof of Theorem 4.7.

We now give a last Ray-Knight theorem from which we will deduce the distribution of  $T^{\mu,a} \equiv \inf\{u ; |B_u| - \mu \ell_u = a\}$ , at least for  $a > 0$ .

**Theorem 3.4 :** Let  $a \geq 0$ , and  $t > 0$  be fixed. Consider  $(B_t; t \geq 0)$  a standard Brownian motion, and  $(\ell_{\tau_t^{\mu,a}}^{\mu,x}; x \in \mathbb{R})$  the family of local times of

$(X_u \equiv |B_u| - \mu \ell_u; u \geq 0)$ , considered at time  $\tau_t^{\mu,a} \equiv \inf\{u : \ell_u^{\mu,a} > t\}$ . Then :

(i) the two processes  $L_t^{a,+} \equiv (\ell_{\tau_t^{\mu,a}}^{\mu,x+a}; x \geq 0)$  and  $L_t^{a,-} \equiv (\ell_{\tau_t^{\mu,a}}^{\mu,a-x}; x \geq 0)$

are independent ;

(ii)  $L_t^{a,+}$  is, as a process in  $x \geq 0$ , a  $BESQ_t^0$  ;

(iii)  $L_t^{a,-}$  is, as a process in  $x \geq 0$ , an inhomogeneous Markov process, which is a  $BESQ_t^2$  on the  $x$ -interval  $[0,a]$ , and a  $BESQ^{2-\frac{2}{\mu}}$  process absorbed at 0 on  $[a,\infty[$ .

From this, we deduce the:

**Corollary 3.4.1 :** Let  $T^{\mu,a} \equiv \inf\{u : |B_u| - \mu \ell_u = a\}$ .

(i) if  $a > 0$ , then,

$$\begin{aligned} E[ \exp(-\frac{\lambda^2}{2} T^{\mu,a}) ] &= \int_0^{+\infty} \frac{(\text{sh}(\lambda a))^{1/\mu} dx}{(\text{sh}(\mu x + \lambda a))^{1+1/\mu}} \\ &= \int_0^{+\infty} dt \exp(-\frac{\lambda^2}{2} t) \sqrt{2/\pi} t^{-3/2} \frac{a}{\mu+1} \sum_{n \geq 0} (2n+1) \frac{\binom{\mu-1}{2\mu}_n}{\binom{3\mu+1}{2\mu}_n} \exp(-a^2(2n+1)^2/2t) \end{aligned}$$

where  $(\alpha)_n \equiv \alpha(\alpha+1)\dots(\alpha+n-1)$ , and  $(\alpha)_0 \equiv 1$ , and,

$$a + \mu \ell_{T^{\mu,a}} \stackrel{(\text{law})}{=} \frac{a}{Z_{1/\mu,1}}$$

(ii) if  $a \leq 0$ ,  $T^{\mu,a}$  has the same law as the first hitting time of  $(-a/\mu)$  by a standard Brownian motion.

Proof : (i) We remark that :  $\tau_0^{\mu,a} \stackrel{\text{def}}{=} \inf\{u ; \ell_u^{\mu,a} > 0\}$  is precisely equal to  $T^{\mu,a}$ . Then, according to Theorem 3.4 and usual computations about squares of Bessel processes, we have:

$$\begin{aligned}
E[ \exp(-\frac{\lambda^2}{2} T^{\mu,a} ) ] &= \lim_{t \rightarrow 0} E[ \exp(-\frac{\lambda^2}{2} \tau_t^{\mu,a} ) ] \\
&= \lim_{t \rightarrow 0} Q_t^0[ \exp(-\frac{\lambda^2}{2} \int_0^{+\infty} Y_x dx) ] Q_t^2[ \exp(-\frac{\lambda^2}{2} \int_0^a Y_x dx) Q_{Y_a}^{2-2/\mu}[ \exp(-\frac{\lambda^2}{2} \int_0^{T_0} Z_x dx) ] ] \\
&= \lim_{t \rightarrow 0} \exp(-\frac{\lambda^2}{2} t) \frac{\Gamma(\frac{\mu+1}{2\mu})}{\sqrt{\pi} \Gamma(\frac{1}{\mu})} Q_t^2[ (\lambda Y_a)^{1/2\mu} K_{1/2\mu}(\frac{\lambda Y_a}{2}) \exp(-\frac{\lambda^2}{2} \int_0^a Y_x dx) ] \\
&= \lim_{t \rightarrow 0} \exp(-\frac{\lambda^2}{2} t) \frac{1}{\Gamma(\frac{1}{2\mu})} \int_0^{+\infty} Q_t^2[ \exp(i\frac{N\lambda}{2} Y_a / \sqrt{2s} - \frac{\lambda^2}{2} \int_0^a Y_x dx) ] e^{-s} s^{1/2\mu-1} ds
\end{aligned}$$

where  $N$  is an independent standard gaussian, centered, reduced variable. The result follows, after computations.

The law of  $T^{\mu,a}$  may also be obtained by the resolution of a Skorohod problem (Jeulin-Yor [6], Proposition 4.4 with  $k(x)=h(x)=\frac{1}{\mu x+a}$ ), which gives the law of  $\ell_{T^{\mu,a}}$ .

(ii) It follows from the equality  $T^{\mu,a} = \tau_{-a/\mu}(B)$ .

In fact from the inequality

$$a = |B_{T^{\mu,a}}| - \mu \ell_{T^{\mu,a}} \geq - \mu \ell_{T^{\mu,a}},$$

we deduce:  $T^{\mu,a} \geq \tau_{-a/\mu}(B)$ .

But, as  $X_{\tau_{-a/\mu}} = |B_{\tau_{-a/\mu}}| - \mu \ell_{\tau_{-a/\mu}} = 0 - \mu(-a/\mu) = a$ ,

we have  $T^{\mu,a} = \tau_{-a/\mu}(B)$ . □

#### 4. Several results about the process $(X_t \equiv |B_t|^{-\mu} ; t \geq 0)$ .

##### (4.1) Towards a general principle ?

After reading sections 2 and 3 above, the reader may come very naturally

to the "conclusion" that, at least as far as the "arc-scenery" is concerned, identities in law valid for Brownian motion (such as (1.d), for instance) "always" extend to the process  $X$ , either literally, or with "little" change. The aim of this section is to show that there is no such "principle", and to present precisely how some of the well-known representations of the Brownian bridge have to be modified in the context of the " $\mu$ -process"  $X$ , conditioned by  $X_1 = 0$ .

#### (4.2) Some notation.

For short, we call  $(X_t^\mu \equiv |B_t| - \mu \ell_t, t \geq 0)$  the  $\mu$ -process ;

- we shall write  $(p_\mu(t), t \leq 1)$  for the  $\mu$ -bridge, i.e. :

the  $\mu$ -process  $(X_t^\mu ; t \leq 1)$  conditioned by :  $X_1^\mu = 0$  ;

- we shall also consider the pseudo- $\mu$ -bridge :

$$\left( p_\mu^\#(t) \stackrel{\text{def}}{=} \frac{1}{\sqrt{t_1^\mu}} X^\mu(t\tau_1^\mu) ; t \leq 1 \right).$$

Now we remark that, in the case  $\mu = 1$ ,  $(X_t, t \geq 0)$  is a 1-dimensional Brownian motion, and the  $(\mu \equiv 1)$ -bridge is simply the Brownian bridge, which we shall denote by  $(p(t) ; t \leq 1)$  ;  $(\lambda_t ; t \leq 1)$  denotes the local time at 0 of  $(p(t) ; t \leq 1)$ .

- finally, it is also natural to introduce the  $\mu$ -process of the Brownian bridge ; precisely :  $(q_\mu(t) \stackrel{\text{def}}{=} (|p(t)| - \mu \lambda_t ; t \leq 1)$ .

#### (4.3) An absolute continuity relationship.

Another fairly straightforward extension of the results valid in the Brownian case ( $\mu = 1$ ) is the following

**Proposition 4.1** : For every measurable functional  $F : C([0,1,\mathbb{R}]) \longrightarrow \mathbb{R}_+$ , we have :

$$(4.a) \quad E[F(p_\mu(t) ; t \leq 1)] = \sqrt{\frac{\pi}{2}} \left( \frac{1+\mu}{2} \right) E \left[ \frac{1}{\sqrt{t_1^\mu}} F(p_\mu^\#(t) ; t \leq 1) \right].$$

Proof : It suffices to follow the steps of the proof in [3] ; here again, as for Proposition 2.1, the scaling property is essential. A unification of these various consequences of the scaling property will be presented in [24].  $\square$

It is easy to show that the local time at 0 of  $(p_\mu^\#(t), t \leq 1)$  is  $\frac{1}{\sqrt{\tau_1^\mu}}$ .

Hence, we deduce from (4.a), with the help of the identity (1.e), the following

**Corollary 4.1.1** : Let  $f : [0,1] \times \mathbb{R}_+ \longrightarrow \mathbb{R}_+$  be a Borel function ; then, we have :

$$(4.b) \quad \mathbb{E} \left[ f \left( \int_0^1 dt \mathbf{1}_{(p_\mu(t) \leq 0)}, \lambda_1^\mu \right) \right] = \sqrt{\frac{\pi}{2}} \left( \frac{1+\mu}{2} \right) \mathbb{E} \left[ f(A_1^{\mu,-}, \ell_1^\mu) \right],$$

where  $(\lambda_t^\mu ; t \leq 1)$  denotes the local time at 0 of  $p_\mu$ .

The absolute continuity relationship (4.a), considered for  $\mu = 1$ , may also be used to obtain the following results concerning the processes  $q_\nu$ .

**Proposition 4.2** : Let  $\nu > 0$ . Define  $A_t^-(q_\nu) \equiv \int_0^t ds \mathbf{1}_{(q_\nu(s) \leq 0)}$ , and let

$(\ell_t^-(q_\nu), t \leq 1)$  be the local time of  $q_\nu$  at 0.

Then, if  $\nu$  and  $\mu$  are related by :  $\frac{1}{\nu} = 1 + \frac{1}{\mu}$ , we have :

$$(4.c) \quad \mathbb{E} \left[ f(A_1^-(q_\nu) ; \ell_1^-(q_\nu)) \right] = \sqrt{\frac{\pi}{2}} \left( \frac{1+\mu}{2} \right) \mathbb{E} \left[ f(A_1^{\mu,-}, \ell_1^\mu) \right]$$

for every Borel function  $f : [0,1] \times \mathbb{R}_+ \longrightarrow \mathbb{R}_+$ .

Comparing relations (4.b) and (4.c), we obtain the following

**Corollary 4.2.1** : If  $\mu$  and  $\nu$  are related by :  $\frac{1}{\nu} = 1 + \frac{1}{\mu}$ , then :

$$(4.d) \quad (A_1(q_\nu) ; \ell_1(q_\nu)) \stackrel{(law)}{=} \left( \int_0^1 dt 1_{(p_\mu(t) \leq 0)} ; \lambda_1^\mu \right).$$

In the particular case  $\mu = 1$ ,  $\nu = \frac{1}{2}$ , the identity in law (4.d) follows from a more general result obtained by Pitman-Yor [17] :

(4.e) *the processes of local times, in the space variable  $x \in \mathbb{R}$ , taken at time 1, of the Brownian bridge  $(p(t) ; t \leq 1)$  and of the process  $(q_{1/2}(t) \equiv |p(t)| - \frac{1}{2} \lambda_t ; t \leq 1)$  are identically distributed.*

The identities in law (4.d) and (4.e) have led us naturally to the following

**Theorem 4.3** : Let  $\nu > 0$ ,  $\mu > 0$  be such that :  $\frac{1}{\nu} = 1 + \frac{1}{\mu}$ .

The processes  $(\ell_1^x(q_\nu) ; x \in \mathbb{R})$  and  $(\ell_1^x(p_\mu) ; x \in \mathbb{R})$  of local times are identically distributed.

Before we prove this theorem, we present another interesting identity in law which follows from Theorem 4.3, and we identify the common distribution.

**Proposition 4.4** : If  $\mu$  and  $\nu$  are related by :  $\frac{1}{\nu} = 1 + \frac{1}{\mu}$ , then :

$$\sup_{0 \leq t \leq 1} p_\mu(t) \stackrel{(law)}{=} \sup_{0 \leq t \leq 1} q_\nu(t) \equiv S_\nu ;$$

furthermore, if  $N$  is a centered reduced gaussian variable, which is independent of  $S_\nu$ , one has :

$$\exp(2|N|S_\nu) - 1 \stackrel{(law)}{=} \left( Z_{1,1/2\nu} \right)^{\frac{1-Z_{1,1/\nu}}{Z_{1,1/\nu}}}$$

where, on the right-hand side, the two beta variables are independent.

Here is now a

Proof of Theorem 4.3 : We will show that for every Borel  $f : \mathbb{R} \longrightarrow \mathbb{R}_+$  we have :

$$(4.f) \quad \mathbb{E} \left[ \exp \left( - \int f(x) \ell_1^x(p_\mu) dx \right) \right] = \mathbb{E} \left[ \exp \left( - \int f(x) \ell_1^x(q_\nu) dx \right) \right].$$

Using the absolute continuity relationship (4.a) considered for a general  $\mu$  and for  $\mu = 1$ , it is equivalent to show :

$$(4.g) \quad \frac{1+\mu}{2} \left[ \frac{1}{\sqrt{\tau_1^\mu}} \exp \left( - \frac{1}{\tau_1^\mu} \int f \left( \frac{x}{\sqrt{\tau_1^\mu}} \right) \ell_{\tau_1^\mu}^x(X^\mu) dx \right) \right] \\ = \mathbb{E} \left[ \frac{1}{\sqrt{\tau_1}} \exp \left( - \frac{1}{\tau_1} \int f \left( \frac{x}{\sqrt{\tau_1}} \right) \ell_{\tau_1}^x(X^\nu) dx \right) \right]$$

Let  $f_\pm : \mathbb{R}_+ \longrightarrow \mathbb{R}_+$  be two Borel functions such that  $f(x) = f_+(x)$  if  $x \geq 0$ ,  $f(x) = f_-(-x)$  if  $x < 0$ . We note :

$$(\tau_1^\mu)^\pm \equiv \int_0^{+\infty} \ell_{\tau_1^\mu}^{\pm x}(X^\mu) dx ; \quad \tau_1^\pm \equiv \int_0^{+\infty} \ell_{\tau_1}^{\pm x}(X^\nu) dx.$$

(Beware  $\tau_1^\pm$  depends on  $\nu$  !)

The main tools we use are :

- i) the scaling property of the square of a Bessel process ;
  - ii) the Ray-Knight theorem which describes the process of the local times of the  $\nu$ -process considered up to time  $\tau_1$ , as an inhomogeneous Markov process (Le Gall-Yor [9]) ;
  - iii) Theorem 9.1 in Chapter 9 of [23] for the local times of the  $\mu$ -process considered up to time  $\tau_1^\mu$  ; this is, in fact, another Ray-Knight theorem.
- Then, we are able to prove the following :

1) the variables  $\frac{\tau_1^+}{[\ell_{\tau_1}^o(X^\nu)]^2}$  and  $\frac{\tau_1^-}{[\ell_{\tau_1}^o(X^\nu)]^2}$  are independent.

More precisely,

$$\begin{aligned}
& \frac{\mu+1}{2} \mathbb{P}[(\tau_1^\mu)^+ \in du] \mathbb{P}[(\tau_1^\mu)^- \in dv] \\
&= \mathbb{E}\left[\left(\ell_{\tau_1}^o(X^\nu)\right)^{-1} \left| \frac{\tau_1^-}{[\ell_{\tau_1}^o(X^\nu)]^2} = v \right. \right] \mathbb{P}\left[\frac{\tau_1^+}{[\ell_{\tau_1}^o(X^\nu)]^2} \in du\right] \mathbb{P}\left[\frac{\tau_1^-}{[\ell_{\tau_1}^o(X^\nu)]^2} \in dv\right] \\
2) & \mathbb{E}\left[\left(\ell_{\tau_1}^o(X^\nu)\right)^{-1} \exp\left(-\int_0^{+\infty} f_+\left(\frac{x}{\ell_{\tau_1}^o(X^\nu)}\right) \frac{\ell_{\tau_1}^x(X^\nu)}{(\ell_{\tau_1}^o(X^\nu))^2} dx\right) \left| \frac{\tau_1^+}{(\ell_{\tau_1}^o(X^\nu))^2} = u, \frac{\tau_1^-}{(\ell_{\tau_1}^o(X^\nu))^2} = v\right.\right] \\
&= \mathbb{Q}_0^{2/\nu}\left[\frac{1}{Y_\nu} \left| \int_0^\nu Y_x dx = v\right.\right] \mathbb{Q}_1^o\left[\exp\left(-\int_0^{+\infty} f_+(x) Y_x dx\right) \left| \int_0^{+\infty} Y_x dx = u\right.\right] \\
&= \mathbb{E}\left[\left(\ell_{\tau_1}^o(X^\nu)\right)^{-1} \left| \frac{\tau_1^-}{(\ell_{\tau_1}^o(X^\nu))^2} = v\right.\right] \mathbb{E}\left[\exp\left(-\int_0^{+\infty} f_+(x) \ell_{\tau_1^\mu}^o(X^\mu) dx\right) \left| (\tau_1^\mu)^+ = u\right.\right]. \\
3) & \mathbb{E}\left[\left(\ell_{\tau_1}^o(X^\nu)\right)^{-1} \exp\left(-\int_0^{+\infty} f_-\left(\frac{x}{\ell_{\tau_1}^o(X^\nu)}\right) \frac{\ell_{\tau_1}^{-x}(X^\nu)}{(\ell_{\tau_1}^o(X^\nu))^2} dx\right) \left| \frac{\tau_1^+}{(\ell_{\tau_1}^o(X^\nu))^2} = u, \frac{\tau_1^-}{(\ell_{\tau_1}^o(X^\nu))^2} = v\right.\right] \\
&= c_\nu \frac{\mathbb{Q}_0^{2/\nu}\left[\int_0^{L_1} Y_x dx \in dv\right]}{\mathbb{Q}_0^{2/\nu}\left[\int_0^\nu Y_x dx = v\right]} \cdot \mathbb{Q}_0^{2/\nu}\left[\exp\left(-\int_0^{L_1} f_-(L_1-x) Y_x dx\right) \left| \int_0^{L_1} Y_x dx = v\right.\right] \\
&= \mathbb{E}\left[\left(\ell_{\tau_1}^o(X^\nu)\right)^{-1} \left| \frac{\tau_1^-}{(\ell_{\tau_1}^o(X^\nu))^2} = v\right.\right] \cdot \mathbb{E}\left[\exp\left(-\int_0^{+\infty} f_-(x) \ell_{\tau_1^\mu}^{-x}(X^\mu) dx\right) \left| (\tau_1^\mu)^- = v\right.\right].
\end{aligned}$$

It now follows that for every Borel function  $\psi : \mathbb{R}_+ \times \mathbb{R}_+ \rightarrow \mathbb{R}_+$  we have :

$$(4.h) \quad \begin{aligned} & \frac{1+\mu}{2} E \left[ \psi((\tau_1^\mu)^+ ; (\tau_1^\mu)^-) \exp\left(-\frac{1}{\tau_1^\mu} \int f\left(\frac{x}{\sqrt{\tau_1^\mu}}\right) \ell_{\tau_1^\mu}^x(X^\mu) dx\right) \right] \\ &= E \left[ \frac{1}{\ell_{\tau_1^0}^0(X^\nu)} \psi\left(\frac{\tau_1^+}{(\ell_{\tau_1^0}^0(X^\nu))^2} ; \frac{\tau_1^-}{(\ell_{\tau_1^0}^0(X^\nu))^2}\right) \exp\left(-\frac{1}{\tau_1} \int f\left(\frac{x}{\sqrt{\tau_1}}\right) \ell_{\tau_1}^x(X^\nu) dx\right) \right] \end{aligned}$$

from which we deduce (4.g) by taking  $\psi(s,t) = \frac{1}{\sqrt{s+t}}$ .  $\square$

#### (4.4) About another proof of the arc sine law.

4.4.1. In the case  $\mu = 1$ , one may prove that  $A_1^- \equiv \int_0^1 ds \mathbf{1}_{(B_s < 0)}$  is arc-sine

distributed by first proving that :  $a^- \equiv \int_0^1 du \mathbf{1}_{(p(u) \leq 0)}$  is uniformly dis-

tributed on  $[0,1]$ , and then using the identity :

$$(4.i) \quad A_1^- \stackrel{\text{(law)}}{\equiv} a^- \cdot g + \varepsilon(1-g),$$

where  $g = \sup\{s < 1 : B_s = 0\}$  is also arc-sine distributed,  $\varepsilon = \mathbf{1}_{(B_1 < 0)}$ , and  $(a^-, g, \varepsilon)$  are independent.

(4.i) follows immediately from the fact that :  $\left(\pi(t) \equiv \frac{1}{\sqrt{g}} B_{tg} ; t \leq 1\right)$  is a

Brownian bridge, which is independent of  $\sigma\{g ; B_{g+u}, u \geq 0\}$ .

Furthermore, the fact that  $a^-$  is uniformly distributed on  $[0,1]$  follows easily from the absolute continuity relationship (4.a), from which we deduce :

$$E[f(a^-)] = \sqrt{\frac{\pi}{2}} E \left[ \frac{1}{\sqrt{\tau(1)}} f\left(\frac{A^-(\tau(1))}{\tau(1)}\right) \right].$$

4.4.2. From the previous subsection, the question arises naturally whether the process :

$$\pi_{\mu}(t) = \frac{1}{\sqrt{g_1^{\mu}}} X^{\mu}(tg_1^{\mu}), \quad t \leq 1, \quad \text{where } g_1^{\mu} = \sup\{t < 1 : X^{\mu}(t) = 0\},$$

is independent from  $\sigma\{g_1^{\mu}; X^{\mu}(g_1^{\mu}+u), u \geq 0\}$ , and also whether  $\pi_{\mu}$  and  $p_{\mu}$  have the same distribution.

To discuss these questions which, as we shall see, have an affirmative answer only in the case  $\mu = 1$ , we shall use again, in an essential way, the scaling property of Brownian motion, which will allow us to express the following expression  $I_{\mu}$  in several different, but equivalent, forms :

$$I_{\mu} \stackrel{\text{def}}{=} \int_0^{+\infty} ds h(s) E \left[ k(g_s^{\mu}) F \left( \frac{1}{\sqrt{g_s^{\mu}}} X^{\mu}(vg_s^{\mu}); v \leq 1 \right) \right],$$

where  $h : \mathbb{R}_+ \rightarrow \mathbb{R}_+$ ,  $k : [0,1] \rightarrow \mathbb{R}_+$  are two Borel functions,

$F : C([0,1], \mathbb{R}) \rightarrow \mathbb{R}_+$  is a measurable functional, and  $g_s^{\mu}$  is the last zero of  $X^{\mu}$  before time  $s$ .

Decomposing the above time integral with respect to the excursions of  $X^{\mu}$  away from 0, we obtain :

$$\begin{aligned} I_{\mu} &= E \left[ \sum_{u>0} \int_{\tau_{u-}^{\mu}}^{\tau_u^{\mu}} ds h(s) k(\tau_{u-}^{\mu}) F \left( \frac{1}{\sqrt{\tau_{u-}^{\mu}}} X^{\mu}(v\tau_{u-}^{\mu}); v \leq 1 \right) \right] \\ (4.j) \quad &= E \left[ \sum_{u>0} k(\tau_{u-}^{\mu}) F \left( \frac{1}{\sqrt{\tau_{u-}^{\mu}}} X^{\mu}(v\tau_{u-}^{\mu}); v \leq 1 \right) \int_0^{\tau_u^{\mu} - \tau_{u-}^{\mu}} ds h(s + \tau_{u-}^{\mu}) \right]. \end{aligned}$$

To simplify notation, we now introduce

$$\varphi_u = k(\tau_{u-}^{\mu}) F \left( \frac{1}{\sqrt{\tau_{u-}^{\mu}}} X^{\mu}(v\tau_{u-}^{\mu}); v \leq 1 \right) \quad (u > 0)$$

which is a previsible process with respect to the filtration  $(\mathcal{F}_{\tau_u^{\mu}}, u \geq 0)$ .

The key to the next developments is the following

**Lemma 4.5** : For every  $\mathbb{R}_+$ -valued process  $(\psi_u ; u > 0)$ , which is previsible with respect to the filtration  $(\mathcal{F}_{\tau_u^\mu} ; u \geq 0)$ , and every Borel function

$h : \mathbb{R}_+ \rightarrow \mathbb{R}_+$ , one has :

$$E \left[ \sum_{u>0} \psi_u \left( \int_0^{\tau_u^\mu - \tau_{u-}^\mu} ds h(s + \tau_{u-}^\mu) \right) \right] = E \left[ \int_0^\infty du \psi_u \int_0^\infty \frac{ds}{\sqrt{s}} h(s + \tau_u^\mu) \theta_\mu \left( \frac{1}{s} (B(\tau_u^\mu))^2 \right) \right]$$

where  $(\theta_\mu(x), x > 0)$  is given by :

$$\theta_\mu(x) = \frac{1}{\sqrt{2\pi}} + \frac{1}{\sqrt{x} B(\frac{1}{2}, \frac{1}{2\mu})} \int_0^{+\infty} |\sin t|^\mu^{-1} \exp\left(-\frac{t^2}{2x}\right) dt.$$

**Remark 4.6** : 1. In the particular case  $\mu = 1$ ,  $\theta_\mu$  is a constant ; precisely,

$\theta_1(x) = \sqrt{\frac{2}{\pi}}$ . A posteriori, we may say that the independence of  $g_1$  and  $\pi_1$  appears as a consequence of the constancy of the function  $\theta_1$  ; of course, there are more direct and well-known proofs of this result, and of the identity in law between  $\pi_1$  and  $p$ . (see, for example, [19], Exercise , p. ).

2. In the language of the general theory of random processes, the identity obtained in Lemma 4.5 is equivalent to the following property :

if  $h : \mathbb{R}_+ \rightarrow \mathbb{R}_+$  is a Borel function, and if we denote  $H(x) = \int_0^x ds h(s)$ , then the  $(\mathcal{F}_{\tau_t^\mu}, t \geq 0)$  predictable projection of  $\sum_{u \leq t} H(\tau_u^\mu - \tau_{u-}^\mu)$  is :

$$\int_0^t du \int_0^{+\infty} \frac{ds}{\sqrt{s}} h(s) \theta_\mu \left( \frac{1}{s} (B(\tau_u^\mu))^2 \right). \quad \square$$

We postpone the proof of the Lemma, and, for the moment, we apply it to  $\psi = \varphi$

in (4.j) in order to relate the laws of  $\pi_\mu$  and  $p_\mu^\#$ , or  $p_\mu$ .

Thus, we obtain :

$$I_\mu = \iint_{\mathbb{R}_+^2} \frac{du ds}{\sqrt{s}} E[k(u^2 \tau_1^\mu) F\left(\frac{X_\mu(v \tau_1^\mu)}{\sqrt{\tau_1^\mu}}; v \leq 1\right) h(s+u^2 \tau_1^\mu) \theta_\mu\left(\frac{u^2}{s} B^2(\tau_1^\mu)\right)]$$

(by scaling).

Making the change of variables  $y = u^2 \tau_1^\mu$  in the integral in (du), we obtain :

$$\begin{aligned} I_\mu &= \iint_{\mathbb{R}_+^2} \frac{dy ds}{2\sqrt{ys}} k(y) E\left[\frac{h(s+y)}{\sqrt{\tau_1^\mu}} \theta_\mu\left(\frac{y}{s} \frac{\mu^2 \ell^2(\tau_1^\mu)}{\tau_1^\mu}\right) F\left(\frac{X_\mu(v \tau_1^\mu)}{\sqrt{\tau_1^\mu}}; v \leq 1\right)\right] \\ &= \iint_{\mathbb{R}_+^2} \frac{k(y) dy ds}{\sqrt{2ys}} h(y+s) E\left[\frac{1}{\sqrt{\tau_1^\mu}} F(p_\mu^\#(v); v \leq 1) \theta_\mu\left(\frac{y}{s} i^2(p_\mu^\#)\right)\right] \end{aligned}$$

where :  $i(p_\mu^\#) = \inf_{s \leq 1} p_\mu^\#(s)$ .

Thus, we obtain :

$$(4.k) \quad I_\mu = \int_0^{+\infty} dt h(t) \int_0^t \frac{dy k(y)}{2\sqrt{y(t-y)}} E\left[\frac{1}{\sqrt{\tau_1^\mu}} F(p_\mu^\#(v); v \leq 1) \theta_\mu\left(\frac{y}{t-y} i^2(p_\mu^\#)\right)\right].$$

On the other hand, from the definition of  $I_\mu$ , we obtain, by scaling :

$$(4.l) \quad I_\mu = \int_0^{+\infty} ds h(s) E[k(s g_1^\mu) F(\pi_\mu(v); v \leq 1)].$$

Now, comparing (4.k) and (4.l), we obtain :

$$\begin{aligned} &E[k(g_1^\mu) F(\pi_\mu(v); v \leq 1)] \\ (4.m) \quad &= \int_0^1 \frac{dy k(y)}{2\sqrt{y(1-y)}} E\left[\frac{1}{\sqrt{\tau_1^\mu}} \theta_\mu\left(\frac{y}{1-y} i^2(p_\mu^\#)\right) F(p_\mu^\#(v); v \leq 1)\right] \end{aligned}$$

$$= \int_0^1 \frac{dy k(y)}{\sqrt{y(1-y)}} c_\mu E \left[ \theta_\mu \left( \frac{y}{1-y} i^2(p_\mu^*) \right) F(p_\mu^*(v) ; v \leq 1) \right]$$

where  $c_\mu = \frac{1}{(1+\mu)} \sqrt{\frac{2}{\pi}}$ , and the equality (4.m) follows from (4.a).

Below, we shall exploit formula (4.m) to describe the law of  $g_1^\mu$  and to relate the laws of  $\pi_\mu$  and  $p_\mu$ .

But, first, we give a proof of Lemma 4.5 which, from well-known arguments relating discontinuous martingales of a "nice" Markov process to its Lévy system (see, e.g., Meyer [12]) may be seen as a consequence of the following partial determination of the infinitesimal generator  $A$  of the two-dimensional Markov process  $(|B_{\tau_t}^\mu|, \tau_t^\mu ; t \geq 0)$ .

**Theorem 4.7 :** *Let  $f : \mathbb{R}_+ \rightarrow \mathbb{R}$  be a  $C^1$  function, with suitable integrability conditions. Then,  $f$ , considered as a function of two variables  $(a, z)$ , belongs to the domain of  $A$ , and :*

$$Af(a, z) = \int_0^{+\infty} f'(z+s) \theta_\mu \left( \frac{a^2}{s} \right) \frac{ds}{\sqrt{s}} .$$

Proof of Theorem 4.7 : We proceed as for the generator of the generalized Watanabe process  $(|B_{\tau_t}^\mu|)_{t \geq 0}$  (see Carmona-Petit-Yor [4], section (4.2)).

Then, we obtain that

the semi-group  $(P_t)_{t \geq 0}$  of the Markov process  $(|B_{\tau_t}^\mu| ; \tau_t^\mu)_{t \geq 0}$  is given by :

$$P_t f(a; z) = E_a \left[ f(|B_{\tau_t}^{\mu, a}| ; z + \tau_t^{\mu, a}) \right]$$

where  $\tau_t^{\mu, a}$  is the inverse of the local time at the point  $a$  of the  $\mu$ -process built with a Brownian motion starting at  $a$ .

In the particular case where  $f(a,z) = \exp(-\frac{\lambda^2}{2} z)$ , we deduce from Theorem 3.3 that :

$$\begin{aligned} P_t f(a;z) &= \exp(-\frac{\lambda^2}{2} z) E_a \left[ \exp(-\frac{\lambda^2}{2} \tau_t^{\mu,a}) \right] \\ &= \exp(-\frac{\lambda^2}{2} z) Q_t^0 \left[ \exp(-\frac{\lambda^2}{2} \int_0^{T_0} Y_x dx) \right] \\ &\times \left\{ Q_t^0 \left[ 1_{T_0 \leq a} \exp(-\frac{\lambda^2}{2} \int_0^{T_0} Y_x dx) \right] + Q_t^0 \left[ 1_{T_0 > a} \exp(-\frac{\lambda^2}{2} \int_0^a Y_x dx) Q_{Y_a}^{2-2/\mu} \left( \exp(-\frac{\lambda^2}{2} \int_0^{T_0} Z_x dx) \right) \right] \right\} \end{aligned}$$

With the calculations made for the proof of the Corollary 3.4.1, we have :

$$P_t f(a;z) = \exp(-\frac{\lambda^2}{2} z) \frac{\exp(-\lambda t/2)}{\Gamma(\frac{1}{2\mu})} \int_0^{+\infty} e^{-s} s^{\frac{1}{2\mu}-1} ds Q_t \left( \exp(-\frac{\lambda^2}{2} \int_0^a Y_u du + \frac{iN\lambda Y_a}{2\sqrt{2s}}) \right)$$

then, with usual computations on Bessel processes,

$$\begin{aligned} Af(a,z) &= \lim_{t \downarrow 0} \exp(-\frac{\lambda^2}{2} z) E_a \left[ \frac{\exp(-\frac{\lambda^2}{2} \tau_t^{\mu,a}) - 1}{t} \right] \\ &= -\lambda^2 \exp(-\frac{\lambda^2}{2} z) E \left[ \frac{1}{\lambda} \left\{ 1 + \frac{\sqrt{2Z_{1/2\mu}} + iN}{\sqrt{2Z_{1/2\mu}} - iN} \exp(-2a\lambda) \right\}^{-1} \right] \end{aligned}$$

where  $N$  is a standard gaussian variable which is independent of  $Z_{1/2\mu}$ .

Then, we develop in serie the term inside the expectation, and we invert the Laplace transforms  $\frac{1}{\lambda} \exp(-2a\lambda)$  in  $\frac{\lambda^2}{2}$ . The theorem follows for each function  $f(a,z)=f(z)$  with suitable integrability conditions, for example, for quickly decreasing functions.  $\square$

We now discuss shortly the identity (4.m).

**Proposition 4.8** : 1) Taking  $F \equiv 1$ , in (4.m), we obtain after some calcula-

tions :

$$(4.n) \quad \mathbb{P}[g_1^\mu \in dy] = c_\mu \frac{1_{]0,1[}(y)dy}{\sqrt{y(1-y)}} E\left[\theta_\mu\left(\frac{y}{1-y} i^2(p_\mu)\right)\right]$$

$$= \frac{1}{\pi(1+\mu)} \frac{dy}{\sqrt{y(1-y)}} 1_{]0,1[}(y) + \frac{\Gamma\left(\frac{\mu+1}{2\mu}\right)^2}{\left|\Gamma\left(\frac{\mu+1}{2\mu}\left(1+i\sqrt{\frac{1-y}{y}}\right)\right)\right|^2} \frac{1_{]0,1[}(y)dy}{2\mu y \operatorname{sh}\left[\pi\frac{\mu+1}{2\mu}\sqrt{\frac{1-y}{y}}\right]}$$

2) The identity (4.m) gives the law of  $(\pi_\mu(v) ; v \leq 1)$  conditionally on  $g_1^\mu$

$$(4.o) \quad E[F(\pi_\mu(v) ; v \leq 1) \mid g_1^\mu = y] = \frac{E\left[\theta_\mu\left(\frac{y}{1-y} i^2(p_\mu)\right) F(p_\mu(v) ; v \leq 1)\right]}{E\left[\theta_\mu\left(\frac{y}{1-y} i^2(p_\mu)\right)\right]}$$

3)  $g_1^\mu$  and  $(\pi_\mu(v) ; v \leq 1)$  are independent conditionally on

$$i(\pi_\mu) \equiv \inf_{v \leq 1} \pi_\mu(v).$$

## 5. Application to Walsh's processes.

We now present some variants for Walsh's Brownian motions and Bessel processes of the results obtained in the previous sections ; we recall (see [1], [2], [20]) that these Markov processes  $(X_t, t \geq 0)$ , which take values in

$E = \bigcup_{i=1}^n I_i$ , the union of  $n$  rays in the plane, are defined as follows :

let  $(p_i ; 1 \leq i \leq n)$  be a probability on  $\{1, 2, \dots, n\}$ . Consider  $n$  rays

$(I_i)_{1 \leq i \leq n}$  meeting at the origin. Suppose  $(X_t)_{t \geq 0}$  starts at the origin, that its radial part is a Bessel process of dimension  $\delta = 2(1-\mu)$ , with  $\delta \in ]0, 2[$ , and that, when  $(X_t)$  reaches the origin, it chooses, at least, heuristically, the  $i^{\text{th}}$  ray  $I_i$  with probability  $p_i$ . This process  $(X_t)_{t \geq 0}$  may be constructed

rigorously using excursion theory : the characteristic (Itô) measure of its excursions away from the origin is given by :  $\sum_{i=1}^n p_i n_i$  , where  $n_i$ , the characteristic measure of excursion in  $I_i$  , is obtained in a canonical way from the measure of excursions of a  $\delta$ -dimensional Bessel process (see [2] for more details). In particular, when  $n = 2$ , and  $\delta = 1$ ,  $(X_t)_{t \geq 0}$  is the so-called skew Brownian motion, with  $P(X_t > 0) = p_1 \equiv p$  and  $P(X_t < 0) = p_2 \equiv 1-p$ . (See Walsh [20]).

Let  $(\ell_t ; t \geq 0)$  be the Markovian local time at 0 of  $(X_t, t \geq 0)$ , or, of its radial part  $(|X_t|, t \geq 0)$  ;  $(\ell_t ; t \geq 0)$  is defined up to a multiplicative constant, which we choose such that  $(\tau_u ; u \geq 0)$ , the right continuous inverse of  $(\ell_t ; t \geq 0)$  be a standard stable subordinator of index  $\mu$ , i.e :

$$E \left[ \exp(-\lambda \tau_u) \right] = \exp(-u \lambda^\mu), \quad , \text{ for every } u \geq 0, \lambda \geq 0.$$

We now define the multidimensional process of times spent in the  $n$  rays :

$$\left( A_t^i = \int_0^t ds \mathbf{1}_{(X_s \in I_i)} ; 1 \leq i \leq n ; t \geq 0 \right).$$

We recall the main result of [2]

**Proposition 5.1** : *Let  $(T_1, T_2, \dots, T_n)$  be  $n$  independent one-sided stable variables of index  $\mu$ . We have, for any fixed  $t > 0$  :*

$$(5.a) \quad \left( \frac{1}{\ell_t^{1/\mu}} A_t^i ; 1 \leq i \leq n \right) \stackrel{(\text{law})}{=} (p_i^{1/\mu} T_i ; 1 \leq i \leq n).$$

We now give a short proof of (4.a), following the method developed above in section 2 for Brownian motion, and in section 3 for the (local time) perturbed reflecting Brownian motion. This proof hinges on the following

**Proposition 5.2** : Let  $F : C([0,1] ; E) \longrightarrow \mathbb{R}_+$  be a measurable functional.

Then :

$$(5.b) \quad E \left[ F(X_u ; u \leq 1) 1_{(X_1 \in I_1)} \right] = E \left[ \frac{1}{\alpha_1^i} F \left( \frac{X_{s\alpha_1^i}}{\sqrt{\alpha_1^i}} ; s \leq 1 \right) \right]$$

where  $(\alpha_t^i ; t \geq 0)$  is the right-continuous inverse of  $(A_u^i ; u \geq 0)$ .

To finish the proof of Proposition 5.1, we use the same arguments as in

paragraph 1.4. We have :  $u = \sum_{j=1}^n A_u^j$ , for  $u \geq 0$ .

Hence :

$$(5.c) \quad \alpha_t^i = t + \sum_{j \neq i} A_{\alpha_t^i}^j = t + \sum_{j \neq i} (A_{\tau}^j)(\ell_{\alpha_t^i}^j).$$

As a consequence of excursion theory, the  $n$  processes

$$\{(A_{\tau}^1)(t) ; (A_{\tau}^2)(t) ; \dots ; (A_{\tau}^n)(t) ; t \geq 0\}$$

are independent, and furthermore,  $(\frac{1}{p_i} (A_{\tau}^i)(t) ; t \geq 0)$  is a standard one-sided stable process of index  $\frac{1}{\mu}$ . We then deduce from (5.b) and (5.c) that,

for every measurable  $f : \mathbb{R}_+^n \longrightarrow \mathbb{R}_+$  :

$$(5.d) \quad E \left[ f \left( \frac{1}{\ell_1^{1/\mu}} (A_1^1 ; \dots ; A_1^n) \right) 1_{(X_1 \in I_1)} \right] = E \left[ \left( \frac{A_{\tau}^i(1)}{\tau(1)} \right) f((A_{\tau}^1)(1), \dots, (A_{\tau}^n)(1)) \right].$$

The identity in law (5.a) follows.

We also deduce from (5.d), just as in the last statement of Corollary 2.1.1. :

$$(5.e) \quad P(X_1 \in I_1 | A_1^i = a ; A_1^j ; \ell_1) = a.$$
